Abstract. We propose an analysis for detecting procedures and goals that are deterministic (i.e., that produce at most one solution at most once), or predicates whose clause tests are mutually exclusive (which implies that at most one of their clauses will succeed) even if they are not deterministic. The analysis takes advantage of the pruning operator in order to improve the detection of mutual exclusion and determinacy. It also supports arithmetic equations and disequations, as well as equations and disequations on terms, for which we give a complete satisfiability testing algorithm, w.r.t. available type information. We have implemented the analysis and integrated it in the CiaoPP system, which also infers automatically the mode and type information that our analysis takes as input. Experiments performed on this implementation show that the analysis is fairly accurate and efficient.

Keywords: Determinacy Inference and Checking, Types.

1 Introduction

Knowing that certain predicates are deterministic for a given class of calls has a number of interesting applications such as detecting programming errors, performing certain high-level program transformations for improving search efficiency, optimizing low level code generation and parallel execution, and estimating tighter upper bounds on the computational costs of goals and data sizes, which can be used for program debugging, resource consumption and granularity control, abstraction carrying code, etc.

By a predicate being deterministic we mean that it produces at most one solution at most once. It is also interesting to detect predicates whose clauses are mutually exclusive (which implies that at most one of them will succeed) even if they are not deterministic because they call other predicates that can produce more than one solution (i.e., that are not deterministic). In this paper we propose a method whereby we can detect procedures and goals that are deterministic, or predicates whose clauses are mutually exclusive. Moreover, we show that, given

(upper approximations of) mode and type information, it is feasible to fully automatize our approach, yielding an effective automatic determinacy analysis.

The rest of this section discusses applications of determinacy information and previous proposals in determinacy detection. The rest of the paper is as follows: Section 2 provides some preliminary definitions which describe the class of types which are handled in our approach and other basic concepts such as tests, and mutual exclusion, Section 3 then explains our algorithm for detecting predicates and goals that are deterministic, Section 4 describes our approach to checking mutual exclusion, Section 5 reports on a prototype implementation which performs the proposed analysis in an automatic way and evaluates the effectiveness and efficiency of our approach showing experimental results, and finally, Section 6 summarizes our conclusions.

1.1 Applications

Perhaps the most important application of compile-time determinacy information is in the context of program development. If we assume that the programmer has indicated that certain predicates should be deterministic for certain calling patterns (using suitable assertions as those used in Ciao [14, 3], Mercury [31], or HAL [8]) and a predicate is determined to be non-deterministic in one of those cases then, clearly, a compile-time error has been detected and can be reported [14, 12]. This is quite useful since certain classes of programming errors often result in turning predicates intended to be deterministic into non-deterministic ones. Also, in addition to detecting programming errors at compile time, determinacy inference can obviously be used to *verify* (i.e., prove correct) such determinacy assertions [14].

Determinacy information can also be used for performing low-level optimizations [32, 25, 31] as well higher-level program transformations for improving search efficiency. In particular, literals can be reordered so that deterministic goals are executed ahead of possibly non-deterministic goals where possible, improving the efficiency of parallel search [30]. Determinacy information is also very useful during program specialization. In addition, the implementation of (and-)parallelism is greatly simplified in presence of determinacy information: knowing that a goal is deterministic allows one to eliminate significant run-time overhead (due to *markers*) [15, 11, 27] and, in addition, performing data parallelism transformations [13].

Finally, determinacy (and mutual exclusion) information can be used to estimate much tighter upper bounds on the computational costs of goals [6]. Since it is generally not known in advance how many of the solutions generated by a predicate will be demanded, a conservative upper bound on the computational cost of a predicate can be obtained by assuming that all solutions are needed, and that all clauses are executed (thus the cost of the predicate is assumed to be the sum of the costs of all of its clauses). It is straightforward to take mutual exclusion into account to obtain a more precise estimate of the cost of a predicate, using the maximum of the costs of mutually exclusive groups of clauses. Moreover, knowing that all literals in a clause will produce at most one

solution allows one to assume that an upper bound on the cost of the clauses is the sum of the cost of all literals in it, which simplifies the cost estimation (as explained in [6]). These upper bounds can be used for improved granularity control of parallel tasks [22] and for better performance/complexity debugging and verification of programs [14, 3].

1.2 Related Work

There has been much interest on determinacy detection in the literature (see [18, 16] and its references), using several different forms of determinism. Arguably, one of the first practical determinacy analyses was the one proposed by Sahlin [29], in the context of the Mixtus partial evaluator. This analysis was later reconstructed and semantically justified, using a denotational semantics of Prolog programs with cut, by Mogensen [24]. The motivation behind this determinacy analysis was, indeed, to be able to unfold predicates with cuts in their clauses. Therefore, the analysis concentrated on the cut and the control flow of the program: interestingly, the proposal in [29] does not take into account predicate arguments. The analysis estimates number of solutions of predicates from a small database of number of possible solutions of built-ins and an analysis of the control structure of the program. The accuracy of this approach has limitations and this is one of the reasons why we explore instead an approach based on the handling of built-ins as tests.

The line of work closest to ours starts with [7], in which functional computations are detected and exploited. However, the notion of mutual exclusion in this work is not based on constraint satisfaction as in our proposal [21] (of which this paper is an extended version). This concept is also used in the analysis presented in [5], where, nonetheless, no algorithms are provided for the detection of mutual exclusion and also the cut is not taken into account. In [10] a combined analysis of modes, types, and determinacy is presented, as well as in the more accurate [2]. As we will show, our analysis improves on these proposals.

A notion of constraint satisfaction is also present in the approach of [23, 18], which might be considered complementary to ours. Their analyses differ from ours in that they are not goal-oriented and in the mutual exclusion conditions. In particular, the first work [23] does not handle the cut, and cannot exploit certain program tests that select clauses on execution (e.g., arithmetic tests) which our proposal handles. The second work [18] remedies these deficiencies. Still, it concentrates on inferring determinacy conditions, not on checking them. The conditions of [18] are richer than ours, since they use success pattern analysis to infer them, based on size relationships between arguments and depth-k abstractions, together with backward analysis. Determinacy conditions are then synthesised in the form of rigidity formulas. For checking them a rigidity analysis is required, to test whether the (propositional) formula holds or not. Instead, we focus on the checking and not on building the conditions. For conditions, we use tests on the instantiation state of arguments which are simply collected from the program text. For the checking, classical mode and type analyses are

instrumental. Indeed, our main contribution is a procedure to check satisfiability of the tests which is complete, disregarding how conditions are synthesised.

Several programming systems also make use of determinacy, e.g., Mercury [31, 12] and HAL [8]. The Mercury and HAL systems allow the programmer to declare that a predicate will produce at most one solution, and attempt to verify this with respect to the Herbrand terms with unification tests. As far as we know, both systems use the same analysis [12], which does not handle disunification tests on the Herbrand domain. This approach also does not handle arithmetic tests, except in the context of the if-then-else construct. As such, it is considerably weaker than the approach described here. Also, our approach does not require any annotations from programmers, since the types and modes on which it is based are *inferred*. In other words, in addition to proposing concrete algorithms, we also show in this paper that our determinacy analysis can be performed automatically, and is feasible, accurate, and efficient. We do this by integrating it into the Ciao programming system, in particular, into its preprocessor, CiaoPP [14], which performs analysis, debugging, verification and optimization tasks, and thus connecting the determinacy analysis with state-of-the-art type and mode analyses.

2 Preliminaries

A goal, a class of goals, or a predicate (i.e., all goals for it) are *deterministic* when they produce at most one solution at most once. When reasoning about determinacy, it is a necessary condition (but not sufficient) that clauses of the predicate be pairwise mutually exclusive, i.e., that only one clause will produce solutions. Additionally, it has to produce only one solution. For reasoning about mutual exclusion one needs to gather success patterns for each predicate clause, i.e., constraints that the solutions produced by the clause satisfy. Then the basic condition for mutual exclusion is that such success patterns cannot be satisfied simultaneously. This is checked for against available information on the goals being analyzed for determinacy.

We will be using as success patterns *tests*, which will be unification equations and disequations on terms, and linear equations and disequations on integers or reals. For the checking, we will assume that type information is available, generally as the result of a previous analysis. For concreteness, the determinacy analysis we describe is based on *regular types* [4], which are specified by *regular term grammars*, as explained below, although the concepts should be easily adaptable to other type systems.

2.1 Regular Types

A type is a set of (Herbrand) terms, and can be defined by using a number of different representations, such as *type terms* and *regular term grammars* as in [4], or *type graphs* as in [17]), or simply predicates as in the Ciao system [3]. We will use the formalism of [4], and summarize below the relevant concepts.

A *type symbol* is an abstraction of a set of Herbrand terms (i.e., of a type). We use the Greek letter α for referring to type symbols in general (with subscripts if necessary). The γ function maps each type symbol to the set of Herbrand terms that it represents. Given a type symbol α , the set of terms (i.e., the type) represented by it is denoted as $\gamma(\alpha)$. To enhance readability, we abuse notation and use α instead of $\gamma(\alpha)$ when no ambiguity is possible.

We assume the existence of an infinite set of *type symbols*, which is disjoint with the sets of constant symbols, function symbols, and variables. There are two special type symbols: μ , that represents the type of the entire Herbrand universe; and ϕ , that represents the empty type (i.e., $\gamma(\phi) = \emptyset$). There is a distinguished non-empty finite subset of the set of type symbols called the set of *base type symbols*, which represent *base types*. We assume that there are effective tests for membership of a given Herbrand term in each base type.

Example 1. Examples of base type symbols that we use in our determinacy analysis are: *int*, such that the base type $\gamma(\text{int})$ is the set of all constant symbols that represent integer numbers; and *atm*, such that the base type $\gamma(\text{atm})$ is the set of all constant symbols that do not represent numbers.

A *type term* is either a constant symbol, a variable, a type symbol, or a term $f(\omega_1, \dots, \omega_n)$, where f is an n -ary function symbol, and each ω_i is a type term. Note that all type symbols are type terms, however, the converse is not true. A *pure type term* is one which does not contain variables. A *Herbrand term* is a type term which does not contain type symbols (it can contain variables).

A *type rule* is an expression of the form $\alpha \rightarrow \mathcal{Y}$, where α is a type symbol, and \mathcal{Y} is a set of pure type terms. We denote sets of type rules, that is, *regular term grammars*, by the letter T (as in [4]). A (non-base) type symbol α is *defined* in, or by, a set of type rules T if there exists a type rule $(\alpha \rightarrow \mathcal{Y}) \in T$. A pure type term ω is *defined* by a set of type rules T if each type symbol in ω is either μ , ϕ , a base type symbol, or a (non-base) type symbol defined in T . We assume that, for each type rule $(\alpha \rightarrow \mathcal{Y}) \in T$, each element (i.e., pure type term) of \mathcal{Y} is defined in T , and that each type symbol defined in T has *exactly* one defining type rule in T . Moreover, we will also assume that every type rule is *deterministic*, i.e., that for every pair of pure type terms $\omega_1, \omega_2 \in \mathcal{Y}$, $\omega_1 \neq \omega_2$, ω_1 and ω_2 have different main functors. The class of types that can be described by deterministic type rules is the same as the class of *tuple-distributive regular types* [4]. Additional background on type-related issues may be found in [4, 17].

Example 2. The type rule $\text{list} \rightarrow \{[], [\mu|\text{list}]\}$ defines the type symbol *list*, that denotes the set of all lists. The type rule $\text{intlist} \rightarrow \{[], [\text{int}|\text{intlist}]\}$ defines the type symbol *intlist*, that denotes the set of all lists of integer numbers.

It is also possible to provide for polymorphism in our setting. Since we use types for describing instantiation patterns, a polymorphic type such as, e.g., $\text{list}(\alpha) \rightarrow \{[], [\alpha|\text{list}(\alpha)]\}$ is useful only in the description of the list structure, but not of the elements. Thus, the instance type $\text{list}(\mu)$ (i.e., *list*) serves the

same purposes. Instances of polymorphic types are thus “computed away” (so that, e.g., $\text{list}(\text{int})$ yields intlist) and our approach handles them in this way.

Given a predicate q in a program P , $\text{type}[q]$ denotes a tuple of pure type terms representing the types of the arguments of predicate q . In the interest of simplicity, we abuse terminology and say that $\text{type}[q]$ is the type of predicate q . In this paper, we are concerned exclusively with *calling types* for predicates—in other words, when we say “a predicate q in a program P has type $\text{type}[q]$ ”, we mean that in any execution of the program P starting from some class of queries of interest, whenever there is a call $q(\bar{t})$ to the predicate q , the argument tuple \bar{t} in the call will be an element of the set denoted by $\text{type}[q]$.

Definition 1 (type assignment). *Given a (finite) tuple of variables $\bar{x} = (x_1, \dots, x_n)$, a type assignment ρ over \bar{x} maps each variable x_i for $1 \leq i \leq n$ to a (nonempty) type term ω_i , i.e., $\rho(x_i) = \omega_i$. We write the type assignment ρ as $\bar{x} : \bar{\omega}$, where $\bar{\omega}$ is the tuple of type terms $(\omega_1, \dots, \omega_n)$.*

2.2 Tests (and Modes)

We define a *test* to be either a primitive test, or a conjunction $\tau_1 \wedge \tau_2$, or a disjunction $\tau_1 \vee \tau_2$, or a negation $\neg \tau_1$, where τ_1 and τ_2 are tests. A *primitive test* is a positive literal whose predicate symbol is a built-in such as the unification or some arithmetic built-in predicate ($<$, $>$, \leq , \geq , \neq , etc.). Primitive tests which are true of the successes of a given clause are gathered together to form the test of that clause. For concreteness, in our experiments (Section 5) we will gather for each clause the primitive tests occurring in the program text of that clause. One could use more sophisticated approaches, such as backwards analysis with a depth- k abstraction [16]. Our approach remains valid regardless of the means used to build the tests. For example, if term structure information is available it will be used in the algorithms below as if it appeared in the program text.

In principle, all primitive tests of a given clause can be used in the test of that clause. However, it turns out that, in practice, because of limitations of state-of-the-art technology in type analysis, primitive tests have to be carefully selected. Actual, working type analyses infer types which denote sets of terms that are closed under substitution. On the contrary, our algorithms will be based on types which denote sets of ground terms. The gap between these two classes of types is covered with the use of modes.

In practice, the difference amounts to the interpretation of the universal type symbol μ . In the ground interpretation, μ denotes the set of all ground terms. Otherwise, μ (i.e., the classical *top* in type analyses) also denotes terms which may contain variables. This issue is important in deciding whether certain (unification) literals can act as tests or not and, therefore, whether they can be used in mutual exclusion conditions or not. For example, consider two tests $\mathbf{X} = [\mathbf{a}]$ and $\mathbf{X} = [\mathbf{b}]$ for different clauses. Assume we are analyzing goals which satisfy the type assignment $(\mathbf{X}) : (\alpha)$ with type rule $\alpha \rightarrow \{\mu\}$. In the ground interpretation the two tests are mutually exclusive, but they are not in the other interpretation

(since the head of the list constructor in X might be a free variable). Mode information is then essential in distinguishing such cases.

In our experiments, we will use groundness and freeness information obtained from a sharing analysis to establish the modes. This information is used to classify primitive tests, and only those regarded as *input tests* will be considered when building tests for clauses. Input tests perform a comparison of (numerical) values or a matching of terms, rather than a proper unification. Given mode and type information on the program, it is straightforward to identify them.

Example 3. Consider the literal $X \text{ is } Y+1$ appearing in the body of a clause. If the available mode and type information asserts that, just before calling this literal, variables X and Y are bound to integer numbers, then the literal is considered a primitive (arithmetic) input test. However, if the mode and type information asserts that X is an unbound variable and Y is bound to an integer, then the literal acts as an assignment and thus is not considered a test. If there is a body literal of the form $X = Y$ and the information asserts that variables X and Y will be bound to ground terms upon call, then the literal is considered to be a primitive (unification) input test. If the information asserts that any of the variables X or Y are free, then the literal is not considered a test.

Where necessary to emphasize the input test in a clause we will write the clause in “guarded” form. As an example, consider a predicate that is called as $\text{abs}(X, Y)$, where X is bound to an integer and Y is a free variable, to obtain the absolute value of X . Its definition will be written as:

$$\begin{aligned} \text{abs}(X, Y) &:- X \geq 0 \parallel Y = X. \\ \text{abs}(X, Y) &:- X < 0 \parallel Y \text{ is } -X. \end{aligned}$$

Obviously, for any particular call in the class above, only one of the tests $X \geq 0$ or $X < 0$ will succeed (i.e., the tests are mutually exclusive).

Note that the distinction between tests and input tests is due only to limitations in the technology used in our experiments. In fact, we will be using the word test throughout the rest of the paper when talking about mutual exclusion conditions. The following definition characterizes tests and will be instrumental in the formal results:

Definition 2 (solutions of a test). *Given a test $\tau(\bar{x})$, $\text{Sols}(\tau(\bar{x}))$ is the set of all tuples of ground terms \bar{e} which are instances of \bar{x} such that $\bar{x} = \bar{e} \wedge \tau(\bar{x})$ is satisfiable (i.e., test $\tau(\bar{e})$ succeeds).*

2.3 Mutual Exclusion

Fundamental to our approach to detecting determinacy is the notion of tests being “exclusive” w.r.t. a type assignment:

Definition 3. *Two tests $\tau_1(\bar{x})$ and $\tau_2(\bar{x})$ are exclusive w.r.t. a type assignment $\bar{x} : \bar{\omega}$, if for every $\bar{t} \in \gamma(\bar{\omega})$, $\bar{x} = \bar{t} \wedge \tau_1(\bar{x}) \wedge \tau_2(\bar{x})$ is unsatisfiable.*

Definition 4 (mutual exclusion). Let C_1, \dots, C_n , $n > 0$, be a sequence of clauses, with input tests $\tau_1(\bar{x}), \dots, \tau_n(\bar{x})$ respectively. Let ρ be a type assignment. We say that C_1, \dots, C_n is mutually exclusive w.r.t. ρ if either, $n = 1$, or, for every pair of clauses C_i and C_j , $1 \leq i, j \leq n$, $i \neq j$, $\tau_i(\bar{x})$ and $\tau_j(\bar{x})$ are exclusive w.r.t. ρ .

Consider a predicate p defined by n clauses C_1, \dots, C_n , with input tests $\tau_1(\bar{x}), \dots, \tau_n(\bar{x})$ respectively. Let predicate p have type $\text{type}[p]$: in the interest of simplicity, we sometimes say that predicate p is mutually exclusive w.r.t. the type $\text{type}[p]$ (or simply that predicate p is mutually exclusive) if the sequence of clauses C_1, \dots, C_n defining p is mutually exclusive w.r.t. the type assignment $\bar{x} : \text{type}[p]$. Given a call c to predicate p in the body of a clause, we also say that c is mutually exclusive if p is. Note that if the predicate p is mutually exclusive, then at most one of its clauses will succeed for any call $p(\bar{t})$, with $\bar{t} \in \gamma(\text{type}[p])$.

3 Determinacy Analysis

In this section we explain our algorithm for detecting predicates and calls that are deterministic. Before introducing our algorithm, we give some instrumental definitions. We define the “calls” relation between predicates in a program as follows: p calls q , written $p \rightsquigarrow q$, if and only if a literal with predicate symbol q appears in the body of a clause defining p . Let \rightsquigarrow^* denote the reflexive transitive closure of \rightsquigarrow . The following result shows the importance of mutual exclusion information for detecting determinacy.

Theorem 1. A predicate p in the program is deterministic if, for each predicate q such that $p \rightsquigarrow^* q$, q is mutually exclusive.

Proof. Assume that p is not deterministic, i.e., there is a goal $p(\bar{t})$, with $\bar{t} \in \gamma(\text{type}[p])$, which is not deterministic. It is a straightforward induction on the number of resolution steps to show that there is a q such that $p \rightsquigarrow^* q$ and q is not mutually exclusive. ■

Our algorithm for detecting determinacy consists of first determining which predicates are mutually exclusive (which is in fact the convoluted part, and is explained in detail in Section 4). Then, inferring determinacy is straightforward: from Theorem 1, analysis of determinacy reduces to the determination of reachability in the call graph of the program. In other words, a predicate p is deterministic if there is no path in the call graph of the program from p to any predicate q that is not mutually exclusive. It is straightforward to propagate this reachability information in a single traversal of the call graph in reverse topological order. The idea is illustrated by the following example.

Example 4. Consider the classical quicksort program with a main calling mode in which the first argument is ground and the second one is free. Figure 1 shows the guarded version of the program for this mode. Assume calling type $(\text{intlist}, -)$ for $\text{qs}/2$. The calling types for $\text{part}/4$ and $\text{app}/3$ are $(\text{intlist}, \text{int}, -, -)$

```

qs(L,SL) :- L = [] || SL = [].
qs(L,SL) :- L = [H|T] || part(H,T,Littles,Bigs),
    qs(Littles,SLs), qs(Bigs,SBs), app(SLs,[H|SBs],SL).

part(L, _C,Left,Right) :- L = [] || Left = [], Right = [].
part(L,C,Left,Right) :- L = [E|R], E < C || Left = [E|Left1],
    part(R,C,Left1,Right).
part(L,C,Left,Right) :- L = [E|R], E >= C || Right = [E|Right1],
    part(R,C,Left,Right1).

app(L1,L2,L3) :- L1 = [] || L2 = L3
app(L1,L2,L3) :- L1 = [X|Xs] || L3 = [X|Zs], app(Xs,L2,Zs).

```

Fig. 1. A quicksort program.

and (`intlist`, `intlist`, `-`) respectively. Since determinacy analysis traverses the call graph in reverse topological order, it considers first predicates `part`/4 and `app`/3.

The input tests for the clauses of `part(L,C,Left,Right)` are $\tau_1^{part}(L,C) \equiv L = []$, $\tau_2^{part}(L,C) \equiv L = [E|R] \wedge E < C$ and $\tau_3^{part}(L,C) \equiv L = [E|R] \wedge E \geq C$. According to the calling type, the analysis uses the type assignment $\rho^{part} \equiv (L,C) : (\text{intlist}, \text{int})$, and infers that $\tau_i^{part}(L,C)$, $i = 1, 2, 3$ are mutually exclusive w.r.t. ρ^{part} (we will explain the details in Section 4). It means that at most one of these tests will succeed. Thus, clauses of `part`/4 are mutually exclusive. It follows that calls to `part`/4 which satisfy the calling types are deterministic.

Similarly, the input tests for the sequence of clauses of `app(L1,L2,L3)` are $\tau_1^{app}(L1,L2) \equiv L1 = []$ and $\tau_2^{app}(L1,L2) \equiv L1 = [X|Xs]$. The type assignment ρ^{app} corresponding to the calling types for `app`/3 is $(L1,L2) : (\text{intlist}, \text{intlist})$. The analysis infers that $\tau_1^{app}(L1,L2)$ and $\tau_2^{app}(L1,L2)$ are exclusive w.r.t. the type assignment ρ^{app} . Thus, it follows that calls to `app`/3 which satisfy the calling types are also deterministic.

Finally, the input tests for the sequence of clauses of `qs(L,SL)` are $\tau_1^{qs}(L) \equiv L = []$ and $\tau_2^{qs}(L) \equiv L = [H|T]$. The type assignment ρ^{qs} corresponding to the calling types is $(L) : (\text{intlist})$. We have that $\tau_1^{qs}(L)$ and $\tau_2^{qs}(L)$ are exclusive w.r.t. type assignment ρ^{qs} . Thus, clauses of `qs`/2 are mutually exclusive. Moreover, since the calls to the predicates `part`/4 and `app`/3 in the body of the clauses defining `qs`/2 have been proved to be deterministic, it follows that calls to `qs`/2 with the first argument bound to a list of integers are deterministic.

3.1 Improving Determinacy Analysis using Cut

The presence of pruning operators in program clauses can be exploited to improve the overall process of detecting deterministic predicates. Besides helping the detection of mutual exclusion of clauses (as we will see below in Section 4.4), it can also improve the propagation algorithm given above. Assume that we want to infer whether a predicate p is deterministic. Consider any clause defining p

in which one or more cuts appear, and any body literals that appear to the left of the rightmost cut in that clause. Those literals are not required to be deterministic. In other words, in Theorem 1, we can use a restricted definition (\leadsto_r) of the “call” relation (\leadsto) between predicates in a program, defined as follows: $p \leadsto_r q$, if and only if a literal with predicate symbol q appears in the body of a clause defining p , and there is no cut to the right of this literal in the clause. Similarly, \leadsto_r^* denotes the reflexive transitive closure of \leadsto_r .

4 Checking Mutual Exclusion

Our approach to the problem of determining whether a set of tests $\tau_i(\bar{x})$ for $i = 1, \dots, n$ are *mutually exclusive* w.r.t. a type assignment $\bar{x} : \bar{\omega}$, consists of reducing the problem to subproblems, each subproblem involving tests of the same type, i.e., defining a particular constraint system. Each subproblem is solved by applying an algorithm that is specific to the corresponding constraint system that checks mutual exclusion. In this paper we consider two commonly encountered constraint systems: Herbrand terms with unification and disunification tests, on variables with *tuple-distributive regular types* [4] (see Section 2.1) and linear arithmetic tests on integer variables.

Example 5. Consider the predicate `part/4` taken from the quicksort program shown in Figure 1. For the sequence of clauses of `part(L,C,Left,Right)` we have three input tests $\tau_i(\bar{x})$, $i = 1, 2, 3$, where $\bar{x} \equiv (\mathbf{L}, \mathbf{C})$ in this case. As commented in Example 4, the input tests are (omitting \bar{x} and the superscript *part* for simplicity): $\tau_1 \equiv \mathbf{L} = []$, $\tau_2 \equiv \mathbf{L} = [\mathbf{E}|\mathbf{R}] \wedge \mathbf{E} < \mathbf{C}$ and $\tau_3 \equiv \mathbf{L} = [\mathbf{E}|\mathbf{R}] \wedge \mathbf{E} >= \mathbf{C}$. We will separate Herbrand tests from arithmetic tests and write τ_1 as $\tau_1^H \wedge \tau_1^A$, where $\tau_1^H \equiv \mathbf{L} = []$ and $\tau_1^A \equiv \text{true}$. Similarly, $\tau_2^H \equiv \mathbf{L} = [\mathbf{E}|\mathbf{R}]$ and $\tau_2^A \equiv \mathbf{E} < \mathbf{C}$, and $\tau_3^H \equiv \mathbf{L} = [\mathbf{E}|\mathbf{R}]$ and $\tau_3^A \equiv \mathbf{E} >= \mathbf{C}$.

We have to check that the tests $\tau_i(\bar{x})$, $i = 1, 2, 3$, are mutually exclusive w.r.t. the type assignment $\rho \equiv (\mathbf{L}, \mathbf{C}) : (\text{intlist}, \text{int})$. This problem is reduced to two subproblems: a) Checking that the tests $\mathbf{L} = []$ and $\mathbf{L} = [\mathbf{E}|\mathbf{R}]$ are exclusive w.r.t. ρ , and b) Checking that the tests $\mathbf{E} < \mathbf{C}$ and $\mathbf{E} >= \mathbf{C}$ are exclusive w.r.t. the type assignment $(\mathbf{C}, \mathbf{E}) : (\text{int}, \text{int})$.

4.1 Checking Mutual Exclusion in the Herbrand Domain

We present a decision procedure for checking mutual exclusion of tests that is inspired by a result, due to Kunen [19], that establishes that the emptiness problem is decidable for Boolean combinations of (notations for) certain “basic” subsets of the Herbrand Universe of a program. It also uses straightforward adaptations of some operations described by Dart and Zobel [4]. The reason the mutual exclusion checking algorithm for Herbrand is as convoluted as it is, is that we want a *complete* algorithm for unification and disunification tests. It is possible to make it more clear if we are interested in unification tests only.

Before describing the algorithm, we introduce some definitions and notation. We denote the Herbrand Universe (i.e., the set of all ground terms) as \mathcal{H} , and

the set of n -tuples of elements of \mathcal{H} as \mathcal{H}^n . We use the notions (to be defined in the following) of *type-annotated term*, and in general *elementary set*, as representations which denote some subsets of \mathcal{H}^n (for some $n \geq 1$). These subsets can be, for example, the set of n -tuples for which a test succeeds, or a calling type for a predicate p (i.e., the set denoted by $\text{type}[p]$). Given a representation S (elementary set or type-annotated term), the denotation of S , $\text{Den}(S)$ refers to the subset of \mathcal{H}^n denoted by S .

Definition 5 (type-annotated term). *A type-annotated term δ is a pair $(\bar{t}_\delta, \rho_\delta)$, where \bar{t}_δ is a tuple of terms, and ρ_δ is a type assignment.*

We will represent type-annotated terms with the symbol δ possibly subscripted. Given a type-annotated term $\delta = (\bar{t}_\delta, \rho_\delta)$, the denotation of δ , $\text{Den}(\delta)$ is the set of all the ground terms $\bar{t}_\delta\theta$, where θ is some substitution, such that $x\theta \in \gamma(\rho_\delta(x))$ for each variable in \bar{t}_δ . In other words, $\text{Den}(\delta)$ is the set of all the ground instances of \bar{t}_δ resulting from replacing the variables in \bar{t}_δ by a term belonging to the type assigned to those variables by ρ_δ .

Example 6. We define some examples of type-annotated terms δ_1 , δ_2 , and δ_3 as follows: $\delta_1 = ((x, y), (x, y) : (\alpha_1, \alpha_2))$, where $\alpha_1 \rightarrow \{f(\mu)\}$ and $\alpha_2 \rightarrow \{g(\mu), h(\mu)\}$; δ_2 is the type-annotated term (\bar{t}_2, ρ_2) such that $\bar{t}_2 \equiv (f(z), w)$ and $\rho_2 \equiv (z, w) : (\mu, \alpha_2)$ (note that δ_1 and δ_2 denote the same subset of \mathcal{H}^2 , i.e., $\text{Den}(\delta_1) = \text{Den}(\delta_2)$); δ_3 is the type-annotated term (\bar{t}_3, ρ_3) with $\bar{t}_3 \equiv (f(v_1), g(v_2), v_3, v_4, f(a), f(v_5), v_6)$ and $\rho_3 \equiv (v_1, v_2, v_3, v_4, v_5, v_6) : (\mu, \text{list}, \alpha_2, \alpha_3, \alpha_3, \text{list})$, where $\alpha_3 \rightarrow \{a, b\}$ and $\text{list} \rightarrow \{[], [\mu|\text{list}]\}$.

Given a type-annotated term (\bar{t}, ρ) , the tuple of terms \bar{t} can be regarded as a Herbrand term (i.e., a type-symbol-free type term) and ρ can be considered to be a *type substitution*,⁴ so that, if we apply this type substitution to \bar{t} , we get a pure type term (a variable-free type term). This is useful for defining the “intersection” and “inclusion” operations over type-annotated terms (that we define later), using the algorithms described by Dart and Zobel [4] for performing these operations over pure type terms. When we have a type-annotated term (\bar{t}, ρ) such that $\rho(x) = \mu$ for each variable x in \bar{t} , we omit the type assignment ρ for brevity and use the tuple of terms \bar{t} . Thus, a tuple of terms \bar{t} with no associated type assignment can be regarded as a type-annotated term which denotes the set of all ground instances of \bar{t} .

Definition 6 (elementary set). *An elementary set is defined as follows:*

- A is an elementary set.
- A type-annotated term (\bar{t}, ρ) is an elementary set.
- If A and B are elementary sets, then $A \otimes B$, $A \oplus B$ and $\text{comp}(A)$ are elementary sets.

⁴ A type substitution is similar to a substitution that maps variables to type terms. A detailed definition of type substitutions is given in [4].

Since we have already defined the denotation of type-annotated terms, we define now the denotation of the rest of elementary sets.

- $Den(A) = \emptyset$ (the empty set).
- If A and B are elementary sets, then $Den(A \otimes B) = Den(A) \cap Den(B)$, $Den(A \oplus B) = Den(A) \cup Den(B)$ and $Den(comp(A)) = \mathcal{H}^n \setminus Den(A)$.

We also define the following relations between elementary sets:

- $A \sqsubseteq B$ iff $Den(A) \subseteq Den(B)$.
- $A \sqsubset B$ iff $Den(A) \subset Den(B)$.
- $A \simeq B$ iff $Den(A) = Den(B)$.

We define below two particular classes of elementary sets, namely, *cobasic sets* and *minsets*, which are suitable representations of tests for the algorithms that we present in this paper. A test $\tau(\bar{x})$ that is a conjunction of unification and disunification tests is represented as a minset that denotes the set of ground instances of \bar{x} (i.e., subsets of \mathcal{H}^n , assuming that \bar{x} is a n -tuple) for which the test succeeds. A disunification test is represented by a cobasic set (which denotes the complementary set of a subset of \mathcal{H}^n).

Definition 7 (cobasic set). A cobasic set is an elementary set of the form $comp(\bar{t})$, where \bar{t} is a tuple of terms.

Definition 8 (minset). A minset is either A or an elementary set of the form $\bar{t}_0 \otimes comp(\bar{t}_1) \otimes \dots \otimes comp(\bar{t}_n)$, for some $n \geq 0$, where:

- \bar{t}_0 is a tuple of terms,
- $comp(\bar{t}_1), \dots, comp(\bar{t}_n)$ are cobasic sets,
- for all $i, 1 \leq i \leq n$, $\bar{t}_i \sqsubset \bar{t}_0$ (which implies that $\bar{t}_i = \bar{t}_0 \theta_i$ for some substitution θ_i), and
- for all i, j such that $1 \leq i, j \leq n$ and $i \neq j$, it holds that $\bar{t}_i \not\sqsubseteq \bar{t}_j$.

For brevity, we write a minset of the form $\bar{t}_0 \otimes comp(\bar{t}_1) \otimes \dots \otimes comp(\bar{t}_n)$ as $\bar{t}_0 \otimes \mathcal{C}$, where $\mathcal{C} = \{comp(\bar{t}_1), \dots, comp(\bar{t}_n)\}$. The minset representation of a test is given by the *test2minset* function defined below.

Definition 9 (exact representation of a test). A minset β is an exact representation of a test $\tau(\bar{x})$ if $Den(\beta) = Sols(\tau(\bar{x}))$. That is, for any tuple of ground terms \bar{e} it holds that $\bar{e} \in Den(\beta)$ if and only if $\bar{x} = \bar{e} \wedge \tau(\bar{x})$ is satisfiable (i.e., the test $\tau(\bar{e})$ succeeds).

Definition 10 (test2minset function). We define the *test2minset*($\tau(\bar{x})$) function which takes a test $\tau(\bar{x})$ and returns a minset β which is an exact representation of $\tau(\bar{x})$. We assume without loss of generality that $\tau(\bar{x})$ is a conjunction of unification and disunification tests and is of the form $\mathcal{E} \wedge \mathcal{D}_1 \wedge \dots \wedge \mathcal{D}_n$, where \mathcal{E} is the conjunction of all unification tests of $\tau(\bar{x})$ (i.e., a system of equations) and each \mathcal{D}_i a disunification test (i.e., a disequation). The returned value β is computed as follows:

1. Let θ_0 be the substitution associated with the solved form of \mathcal{E} (this can be computed by using the techniques of Lassez et al. [20]).
2. If θ_0 does not exist, then make $\beta = \Lambda$.
3. Otherwise, let θ_i , for $1 \leq i \leq n$, be the substitution associated with the solved form of $\mathcal{E} \wedge \mathcal{N}_i$, where \mathcal{N}_i is the negation of \mathcal{D}_i .
4. Let $\beta' = \bar{t}_0 \otimes \text{comp}(\bar{t}_1) \otimes \cdots \otimes \text{comp}(\bar{t}_n)$, where $\bar{t}_i = \bar{x}\theta_i$, if θ_i exists, for $0 \leq i \leq n$ (if θ_i does not exist, then $\text{comp}(\bar{t}_i)$ does not appear in the definition of β').
5. If $\bar{t}_0 \sqsubseteq \bar{t}_i$, for some cobasic set $\text{comp}(\bar{t}_i)$, then make $\beta = \Lambda$.
6. Otherwise, perform a simplification step on β' by removing all cobasic sets $\text{comp}(\bar{t}_i)$ for which there is a cobasic set $\text{comp}(\bar{t}_j)$, $1 \leq i, j \leq n$ and $i \neq j$, such that $\bar{t}_i \sqsubseteq \bar{t}_j$. Make β be the resulting minset.

Theorem 2. Let $\tau(\bar{x})$ be a conjunction of unification and disunification tests, and $\beta = \text{test2minset}(\tau(\bar{x}))$. Then β is an exact representation of $\tau(\bar{x})$.

Proof.

- Since we use the techniques of Lassez et al. [20] for computing solved forms of systems of equations over Herbrand terms, it follows that if θ_0 does not exist (step 2), then \mathcal{E} is unsatisfiable and hence $\tau(\bar{x})$ also is, thus $\beta = \Lambda$ is an exact representation of $\tau(\bar{x})$.
- For the same reason, if θ_0 exists (step 3), then it is a most general unifier, and thus \bar{t}_0 is an exact representation of \mathcal{E} . We can prove it because for any tuple of ground terms \bar{e} it holds that if $\bar{e} \in \text{Den}(\bar{t}_0)$ then $\bar{e} = \bar{t}_0\theta_e$ for some ground substitution θ_e . Since $\bar{t}_0 = \bar{x}\theta_0$, we have that $\bar{e} = \bar{x}\theta_0\theta_e$. Let $\theta'_e = \theta_e \circ \theta_0$, i.e., $\bar{e} = \bar{x}\theta'_e$. By definition, θ_0 is more general than θ'_e , and thus $\bar{x} = \bar{e} \wedge \mathcal{E}$ is satisfiable. Conversely, if $\bar{x} = \bar{e} \wedge \mathcal{E}$ is satisfiable then $\bar{e} = \bar{x}\theta'_e$ for some ground substitution θ'_e which is more specific than θ_0 , i.e., $\theta'_e = \theta_e \circ \theta_0$, thus $\bar{e} \in \text{Den}(\bar{t}_0)$.
- In step 4 we have that $\text{Den}(\beta') = \text{Den}(\bar{t}_0 \otimes \text{comp}(\bar{t}_1) \otimes \cdots \otimes \text{comp}(\bar{t}_n)) = \text{Den}((\bar{t}_0 \otimes \text{comp}(\bar{t}_1)) \otimes \cdots \otimes (\bar{t}_0 \otimes \text{comp}(\bar{t}_n))) = \text{Den}(\bar{t}_0 \otimes \text{comp}(\bar{t}_1)) \cap \cdots \cap \text{Den}(\bar{t}_0 \otimes \text{comp}(\bar{t}_n)) = \text{Sols}(\mathcal{E} \wedge \mathcal{D}_1) \cap \cdots \cap \text{Sols}(\mathcal{E} \wedge \mathcal{D}_n) = \text{Sols}(\mathcal{E} \wedge \mathcal{D}_1 \wedge \cdots \wedge \mathcal{D}_n) = \text{Sols}(\tau(\bar{x}))$.
- In step 5 we have that if $\bar{t}_0 \sqsubseteq \bar{t}_i$, for some cobasic set $\text{comp}(\bar{t}_i)$, then $\text{Den}(\bar{t}_0) \subseteq \text{Den}(\bar{t}_i)$ and $\text{Den}(\bar{t}_0 \otimes \text{comp}(\bar{t}_i)) = \text{Den}(\bar{t}_0) \cap \text{Den}(\text{comp}(\bar{t}_i)) = \emptyset = \text{Sols}(\mathcal{E} \wedge \mathcal{D}_i)$. Thus $\text{Den}(\beta) = \emptyset = \text{Sols}(\tau(\bar{x}))$.
- In step 6, if $\bar{t}_i \sqsubseteq \bar{t}_j$, then $\text{Den}(\text{comp}(\bar{t}_i)) \subseteq \text{Den}(\text{comp}(\bar{t}_j))$ and $\text{Den}(\bar{t}_0 \otimes \text{comp}(\bar{t}_i)) \cap \text{Den}(\bar{t}_0 \otimes \text{comp}(\bar{t}_j)) = \text{Den}(\bar{t}_0 \otimes \text{comp}(\bar{t}_j))$, thus $\text{Den}(\beta) = \text{Den}(\beta')$. ■

Example 7. In order to illustrate the construction of minsets we have created the program below, instead of using the previous quicksort program or a real application. This program exhibits features that can appear in different real cases, and thus allows us to illustrate almost all cases of the algorithm using a single example.

$\text{p}(\text{X1}, \text{X2}, \text{X3}) :- \text{X1} = \text{f}(\text{Y1}, \text{Y2}), \text{Y1} \neq \text{r}(\text{Z1}), \text{Y2} \neq \text{s}(\text{Z2}) \parallel \text{X3} = \text{a}.$
 $\text{p}(\text{X1}, \text{X2}, \text{X3}) :- \text{X1} = \text{f}(\text{Y1}, \text{Y2}), \text{Y1} = \text{s}(\text{Z1}), \text{Y2} \neq \text{r}(\text{Z2}) \parallel \text{X3} = \text{b}.$

The guarded program assumes a mode in which the first two arguments of $\mathbf{p}/3$ are ground and the third one is free. Let the calling type be $(\alpha_1, \alpha_1, -)$, where the type symbols α_1 and α_2 are defined as follows:

$$\alpha_1 \rightarrow \{f(\alpha_2, \alpha_2), g(\alpha_2, \alpha_2)\} \quad \alpha_2 \rightarrow \{r(\mu), s(\mu)\}$$

Let us take $\tau(\bar{x})$ in $\text{test2minset}(\tau(\bar{x}))$ to be the test of the first clause of $\mathbf{p}/3$. That is, $\bar{x} = (X1, X2)$ and $\tau(\bar{x}) = \tau(X1, X2) \equiv X1 = f(Y1, Y2) \wedge Y1 \neq r(Z1) \wedge Y2 \neq s(Z2)$. We have that $\tau(X1, X2)$ is written as $\mathcal{E} \wedge \mathcal{D}_1 \wedge \mathcal{D}_2$, where $\mathcal{E} \equiv X1 = f(Y1, Y2)$, $\mathcal{D}_1 \equiv Y1 \neq r(Z1)$ and $\mathcal{D}_2 \equiv Y2 \neq s(Z2)$. The minset β which represents $\tau(X1, X2)$ is computed as follows:

1. $\theta_0 = \{X1 = f(Y1, Y2)\}$
2. $\theta_1 = \{X1 = f(r(Z1), Y2), Y1 = r(Z1)\}$ is the substitution associated with the solved form of $X1 = f(Y1, Y2) \wedge Y1 = r(Z1)$, i.e., the system of equations $\mathcal{E} \wedge \mathcal{N}_1$, where \mathcal{N}_1 is the negation of $Y1 \neq r(Z1)$.
3. $\theta_2 = \{X1 = f(Y1, s(Z2)), Y2 = s(Z2)\}$ is the substitution associated with the solved form of $X1 = f(Y1, Y2) \wedge Y2 = s(Z2)$.
4. Applying θ_0 to $(X1, X2)$ we obtain \bar{t}_0 , i.e., $(f(Y1, Y2), X2)$. Also, $\bar{x}\theta_1 = \bar{t}_1 = (f(r(Z1), Y2), X2)$ and $\bar{x}\theta_2 = \bar{t}_2 = (f(Y1, s(Z2)), X2)$. Thus $\beta' = (f(Y1, Y2), X2) \otimes \text{comp}((f(r(Z1), Y2), X2)) \otimes \text{comp}((f(Y1, s(Z2)), X2))$.
5. Finally, the simplification steps does not remove any cobasic set from β' , thus $\beta = \beta'$.

If we apply the algorithm to the second clause, we obtain the minset: $(f(s(Z1), Y2), X2) \otimes \text{comp}((f(s(Z1), r(Z2)), X2))$.

Definition 11 (type-annotated term instance). Let $\delta_1 = (\bar{t}_1, \rho_1)$ and $\delta_2 = (\bar{t}_2, \rho_2)$ be two type-annotated terms. We say that δ_1 is an instance of δ_2 if $\delta_1 \sqsubseteq \delta_2$ and there is a substitution θ such that $\bar{t}_1 = \bar{t}_2\theta$.

Reduction of the Checking Exclusion Problem

Let $\tau_1(\bar{x})$ and $\tau_2(\bar{x})$ be tests which are conjunctions of unification and disunification tests, and ρ a type assignment. Let δ be a type-annotated term representing the type assignment ρ . Let β_i be a minset representing τ_i , for $i = 1, 2$, i.e., $\beta_i = \text{test2minset}(\tau_i)$ (where the test2minset function is given in Definition 10). We have that $\tau_1(\bar{x})$ and $\tau_2(\bar{x})$ are exclusive w.r.t. ρ if and only if $\delta \otimes \beta_1 \otimes \beta_2 \simeq A$. Let β be the minset resulting of computing $\beta_1 \otimes \beta_2$ (this intersection can be trivially defined in terms of most general unifiers of the tuples of terms composing the minsets β_1 and β_2). Then, the fundamental problem is to devise an algorithm to test whether $\delta \otimes \beta \simeq A$, where δ is a type-annotated term and β a minset.

Example 8. Consider the mutual exclusion problem for the input tests and calling type given in Example 7 for predicate $\mathbf{p}/3$. Such calling type is written as the type assignment $((X1, X2) : (\alpha_1, \alpha_1))$, which is represented as the type-annotated term δ , where $\delta = ((X1, X2), (X1 : \alpha_1, X2 : \alpha_1))$. The tests and minsets representing them respectively are:

$\tau_1(\bar{x}) = \tau_1(X1, X2) \equiv X1 = f(Y1, Y2) \wedge Y1 \neq r(Z1) \wedge Y2 \neq s(Z2),$
 $\tau_2(\bar{x}) = \tau_2(X1, X2) \equiv X1 = f(Y1, Y2) \wedge Y1 = s(Z1) \wedge Y2 \neq r(Z2),$
 $\beta_1 = (f(Y1, Y2), X2) \otimes comp((f(r(Z1), Y2), X2)) \otimes comp((f(Y1, s(Z2)), X2)),$ and
 $\beta_2 = (f(s(Z1), Y2), X2) \otimes comp((f(s(Z1), r(Z2)), X2)).$
 Thus, $\beta \simeq \beta_1 \otimes \beta_2 \equiv (f(s(X3), X4), X5) \otimes comp(f(s(X6), s(X7)), X8) \otimes comp(f(s(X9), r(X10)), X11).$

A High Level Description of the Algorithm

We first provide a high level description of the algorithm that we propose, whose detailed description for its implementation is given by the boolean function *empty*(δ, β) in Definitions 16, 17 and 18:⁵ Assume that $\beta = \bar{t}_0 \otimes \mathcal{C}$ and that $\beta \not\subseteq A$.

- First, perform the intersection of the type-annotated term δ and the tuple of terms \bar{t}_0 of the minset β (i.e., obtain a type-annotated term δ' such that $\delta' = \delta \otimes \bar{t}_0$). This operation is implemented by the *intersec* function described in Definition 14.
- If δ' is empty (i.e., $\delta' \simeq A$) then it can be reported that $\delta \otimes \beta \simeq A$. Otherwise, if \bar{t}_0 is included in δ' (i.e., $\bar{t}_0 \sqsubseteq \delta'$) then it can be reported that $\delta \otimes \beta \not\subseteq A$ (note that it always holds that $\beta \sqsubseteq \bar{t}_0$). Our inclusion operation will be the *included* function.
- Otherwise, the problem is reduced to checking whether $\delta' \otimes \mathcal{C} \simeq A$ (this is done by the auxiliary function *empty1*, described in detail in Definition 17). Note that $\delta' \otimes \mathcal{C}$ can be seen as a system of one equation (corresponding to δ') and zero or more disequations (each of them corresponding to a cobasic set in \mathcal{C}). Thus the problem can be seen as determining whether such system has no solutions.
- Thus, if δ' is included in the tuple of terms of some cobasic set in \mathcal{C} , then it can be reported that $\delta' \otimes \mathcal{C} \simeq A$.
- Otherwise, it means that δ' is “too big”, and thus, it is “expanded” to a set of “smaller” type-annotated terms with the hope that each of them will be included in the tuple of terms of some cobasic set in \mathcal{C} . This way, the initial problem is reduced to a finite number of subproblems, one subproblem for each element in the set of type-annotated terms to which δ' has been “expanded”.

Example 9. Consider for example δ and β given in Example 8. In this case, \bar{t}_0 denotes the tuple of terms $(f(s(X3), X4), X5)$ and \mathcal{C} denotes the set of cobasic sets $\{comp(f(s(X6), s(X7)), X8), comp(f(s(X9), r(X10)), X11)\}$. Thus, the intersection of δ and \bar{t}_0 is the type-annotated term $\delta' = ((f(s(X12), X13), X14), (X12 : \mu, X13 : \alpha_2, X14 : \alpha_1).$

⁵ We use the type representation of [4], and assume that there is a common set of rules where type symbols are described. For brevity, we omit such set of type rules in the description of the algorithms.

Now, neither this term δ' is empty nor does it include \bar{t}_0 . It is then considered “too big” and therefore “expanded” to a set of two “smaller” type-annotated terms $\{\delta'_1, \delta'_2\}$ (expanding variable X_{13}) where δ'_1 denotes the term $((f(s(X_{15}), r(X_{16})), X_{17}), (X_{15} : \mu, X_{16} : \mu, X_{17} : \alpha_1))$ and δ'_2 denotes the term $((f(s(X_{18}), s(X_{19})), X_{20}), (X_{18} : \mu, X_{19} : \mu, X_{20} : \alpha_1))$. Then, two subproblems arise:

- Checking whether $\delta'_1 \otimes \text{comp}(f(s(X_6), r(X_7)), X_8) \simeq A$, which holds because δ'_1 is included in $(f(s(X_6), r(X_7)), X_8)$, the tuple of terms of the cobasic set $\text{comp}(f(s(X_6), r(X_7)), X_8)$; and
- Checking whether $\delta'_2 \otimes \text{comp}(f(s(X_9), r(X_{10})), X_{11}) \simeq A$ is empty, which also holds because δ'_2 is included in $(f(s(X_9), r(X_{10})), X_{11})$.

Thus, it can be concluded that $\delta' \otimes C \simeq A$ and hence $\delta \otimes \beta \simeq A$.

A Detailed Description of the Algorithm

The function $\text{empty}(\delta, \beta)$ is based essentially on detecting “useless” cobasic sets, which cannot include the types of δ that are being analyzed. The formal definition of “useless” is given below, together with a definition of function *included* and those for the *intersec* and *expansion* functions, as well as the instrumental function *aliased*.

The inclusion operation for two type-annotated terms δ_1 and δ_2 can be defined by using a straightforward adaptation of the subset_T function described in [4], that determines whether the type denoted by a pure type term is a subset of the type denoted by another. The resulting function $\text{included}(\delta_1, \delta_2)$ returns **true** if and only if $\delta_1 \sqsubseteq \delta_2$.

Definition 12 (useless cobasic set). *Given a type-annotated term δ , a set of cobasic sets C , and a cobasic set $\text{comp}(\bar{t}) \in C$, we say that $\text{comp}(\bar{t})$ is useless for determining whether $\delta \otimes C \simeq A$, whenever if $\delta \otimes (C - \{\text{comp}(\bar{t})\}) \not\simeq A$, then $\delta \otimes C \not\simeq A$ (or, equivalently, if $\delta \otimes C \simeq A$, then $\delta \otimes (C - \{\text{comp}(\bar{t})\}) \simeq A$).*

It is easy to prove that the reciprocal also holds. If $\delta \otimes (C - \{\text{comp}(\bar{t})\}) \simeq A$, then obviously $\delta \otimes C \simeq A$ (note that $(\delta \otimes C) \sqsubseteq (\delta \otimes (C - \{\text{comp}(\bar{t})\}))$). Thus, if $\text{comp}(\bar{t}) \in C$ is an useless cobasic set, then $\delta \otimes C \simeq A$ if and only if $\delta \otimes (C - \{\text{comp}(\bar{t})\}) \simeq A$.

Definition 13 (aliased(δ, \bar{t}) function). *Let δ be the type-annotated term $(\bar{t}_\delta, \rho_\delta)$, $\delta \not\simeq A$, \bar{t} a tuple of terms, and $\theta = \text{mgu}(\bar{t}_\delta, \bar{t})$. We define the aliased function as follows:*

$$\text{aliased}(\delta, \bar{t}) = \{ x \in \text{vars}(\bar{t}_\delta) \mid x\theta \text{ is a variable, and exists } x' \in \text{vars}(\bar{t}_\delta), x \neq x', \text{ such that } x\theta = x'\theta \}.$$

Given a type-annotated term δ and a tuple of terms \bar{t} , the $\text{intersec}(\delta, \bar{t})$ function returns a type-annotated term whose meaning is the same as $\delta \otimes \bar{t}$ (recall that a tuple of terms is also a type-annotated term). This function can be defined as a straightforward adaptation of the $\text{unify}(\omega_1, \omega_2, T, \Theta)$ function

described in [4], that performs a *type unification*, where ω_1 and ω_2 are the type terms to be unified, Θ a type substitution for the variables in ω_1 and ω_2 , and T a set of type rules defining the type symbols appearing in $\omega_1\Theta$, $\omega_2\Theta$, and Θ . The output of the function *unify* is a triple $(\omega_f, T_f, \Theta_f)$, where ω_f is a type term, Θ_f a type substitution for the variables in ω_f , and T_f a set of type rules defining the type symbols appearing in the pure type term $\omega_f\Theta_f$, such that $T \subseteq T_f$. Since type terms can be trivially rewritten as type-annotated terms, we can define function *intersec* (δ, \bar{t}) as follows:

Definition 14 (*intersec* (δ, \bar{t}) function).

Given a type-annotated term δ and a tuple of terms \bar{t} , the process of function *intersec* (δ, \bar{t}) is:

- Let δ be the pair $(\bar{t}_\delta, \rho_\delta)$, and $(\omega_f, T_f, \Theta_f) = \text{unify}(\bar{t}_\delta, \bar{t}, T, \Theta)$ (note that a tuple of terms is a particular case of type term, and that \bar{t}_δ and \bar{t} are tuples of terms), where Θ is a type substitution constructed as follows:

$$x\Theta = \begin{cases} \omega & \text{if } x \in \text{vars}(\delta) \text{ and } \rho_\delta(x) = \omega \\ x & \text{otherwise.} \end{cases}$$

and T a set of type rules defining the type symbols in $\bar{t}_\delta\Theta$.

- Rewrite $\omega_f\Theta_f$ as a type-annotated term δ' and return it. For simplicity, we assume that the function returns only a type-annotated term δ' , but in fact it returns a pair (δ', T_f) , where T_f is a set of type rules defining the type symbols appearing in δ' .

Theorem 3. Given a type-annotated term δ and a tuple of terms \bar{t} , then: (i) *intersec* (δ, \bar{t}) terminates, (ii) *intersec* $(\delta, \bar{t}) \simeq \delta \otimes \bar{t}$, and (iii) *intersec* $(\delta, \bar{t}) = \Lambda$ iff $\delta \otimes \bar{t} \simeq \Lambda$.

Proof. It follows from Theorem 5.60 of [4], since the function *intersec* is an adaptation of the function *unify* $(\omega_1, \omega_2, T, \Theta)$. ■

Definition 15 (*expansion function*). Let δ be a type-annotated term $(\bar{t}_\delta, \rho_\delta)$, $\delta \not\simeq \Lambda$, and *comp* (\bar{t}) a cobasic set. We define function *expansion* as:

expansion $(\delta, \text{comp}(\bar{t})) = (\delta', \Delta)$, where (δ', Δ) is a “partition” of δ , i.e.:

- δ' is a type-annotated term instance of δ , $(\bar{t}_{\delta'}, \rho_{\delta'})$, $\delta' \not\simeq \Lambda$. δ' is obtained by expanding δ to some “decision depth” that allows to detect if the cobasic set *comp* (\bar{t}) is useless (see Definition 12 of useless cobasic set);
- Δ is a set of type-annotated terms;
- for all $x \in \text{vars}(\delta')$, it holds that: $\rho_{\delta'}(x) = \mu$, or $x\theta$ is a variable, where θ is the most general unifier of $\bar{t}_{\delta'}$ and \bar{t} (note that the variables of δ whose type is μ are not “expanded”);
- $(\cup_{\delta'' \in \Delta} \text{Den}(\delta'')) \cup \text{Den}(\delta') = \text{Den}(\delta)$ (i.e., $\delta \simeq (\bigoplus_{\delta'' \in \Delta} \delta'') \oplus \delta'$); and
- for all $\delta'' \in \Delta$, $\delta'' \otimes \bar{t} \simeq \Lambda$ (this is ensured because type rules are deterministic).

We do not describe the process of the expansion function because it is trivial.

Definition 16 (*empty*(δ, β) **function**). Given a type-annotated term δ and a minset β such that $\beta \not\sqsubseteq \Lambda$ ($\beta = \bar{t}_0 \otimes \mathcal{C}$, where \bar{t}_0 is a tuple of terms, and \mathcal{C} a set of cobasic sets), we define:

$$\text{empty}(\delta, \beta) = \left\{ \begin{array}{ll} \text{true} & \text{if } \delta' = \Lambda \\ \text{false} & \text{if } \text{included}(\bar{t}_0, \delta') \\ \text{empty1}(\mathcal{C}, \delta', \emptyset) & \text{otherwise} \end{array} \right\} \quad \delta' = \text{intersec}(\delta, \bar{t}_0)$$

Definition 17 (*empty1*($\mathcal{C}, \delta, \Gamma$) **function**). Given a type-annotated term δ (i.e., a pair $(\bar{t}_\delta, \rho_\delta)$) such that $\delta \not\sqsubseteq \Lambda$, a set of cobasic sets \mathcal{C} , and a set Γ of triples of the form $(\delta_1, \mathcal{V}, \text{comp}(\bar{t}))$ where:

- δ_1 is a type-annotated term $\delta_1 = (\bar{t}_1, \rho_1)$, such that $\delta_1 \not\sqsubseteq \Lambda$,
- $\text{comp}(\bar{t})$ is a cobasic set,
- $\text{vars}(\delta_1) \cap \text{vars}(\text{comp}(\bar{t})) = \emptyset$,
- $\theta = \text{mgu}(\bar{t}_1, \bar{t})$,
- for all $x \in \text{vars}(\delta_1)$, $x\theta$ is a variable, and
- $v \in \mathcal{V}$ iff $v \in \text{vars}(\delta_1)$, $\rho_{\delta_1}(v) \neq \mu$ and $\exists v' \in \text{vars}(\delta_1)$, $v \neq v'$, such that $v\theta = v'\theta$ (i.e., \mathcal{V} is the set of variables in $\text{vars}(\delta_1)$ which are aliased with some other variable in $\text{vars}(\delta_1)$ by θ).

we define the *empty1* function in Algorithm 1.

The *empty1*($\mathcal{C}, \delta, \Gamma$) function performs a “first pass” over the cobasic sets in \mathcal{C} . This pass results in the removal of cobasic sets that are inferred to be useless. Some useless cobasic sets are removed in step 1: if $\text{intersec}(\delta, \bar{t}) = \Lambda$, for some $\text{comp}(\bar{t}) \in \mathcal{C}$, then $\text{comp}(\bar{t})$ is useless for determining whether $\delta \otimes \mathcal{C} \simeq \Lambda$, because none of the instances of δ meet the equality constraint imposed by \bar{t} , and hence all the instances of δ meet the inequality constraint imposed by $\text{comp}(\bar{t})$. Thus, $\delta \otimes \mathcal{C} \simeq \Lambda$ if and only if the rest of cobasic sets, $\mathcal{C} - \{\text{comp}(\bar{t})\}$, impose (inequality) constraints that are not met by any instance of δ .

If $\text{included}(\delta, \bar{t})$ for some cobasic set $\text{comp}(\bar{t})$ in \mathcal{C}' (as it is checked in step 6), then all the instances of δ meet the equality constraint imposed by \bar{t} , and hence, none of the instances of δ meet the inequality constraint imposed by $\text{comp}(\bar{t})$. Thus, in this case, $\delta \otimes \mathcal{C} \simeq \Lambda$.

The rationale behind steps 9 to 11 is that at this point (where not $\text{included}(\delta, \bar{t})$ nor $\text{intersec}(\delta, \bar{t}) = \Lambda$) δ is “too big,” and thus it is “expanded” to a set of “smaller” type-annotated terms $\{\delta'\} \cup \Delta$ (using the *expansion* function given in definition 15), in the hope that each of them will be “included” in the tuple of terms of some cobasic set in \mathcal{C}' . In this expansion, δ' is obtained by expanding variables $v \in \text{vars}(\delta)$ to at most a depth given by $v\sigma$, where $\sigma = \text{mgu}(\bar{t}_\delta, \bar{t})$. When inclusion is checked at step 12, if $\text{included}(\delta', \bar{t})$, then necessarily for all $x \in \text{vars}(\delta')$ it holds that $x\theta'$ is a variable, where $\theta' = \text{mgu}(\bar{t}_{\delta'}, \bar{t})$ (step 16). In this case, $\text{comp}(\bar{t})$ is not considered in the recursive calls in step 13 since (according to definition 15) for all $\delta'' \in \Delta$, $\delta'' \otimes \bar{t} \simeq \Lambda$, and thus, $\text{comp}(\bar{t})$ is useless for all of these subproblems. If not $\text{included}(\delta', \bar{t})$, then: a) \bar{t} imposes

some equality constraints over some variables in δ (such variables are gathered together in step 15, where the set \mathcal{V} is created using the *aliased* function given in Definition 13), or b) \bar{t} restricts the values of some variable(s) in δ' whose type is μ , unifying them to some term (which is not a variable). If the condition checked at step 17 holds, then there is always an instance of δ' which does not meet the former constraints a) or b), and thus $\text{comp}(\bar{t})$ is useless.

In step 20, cobasic sets which are not deemed useless at this point are stored in Γ , which is an accumulation parameter. δ' and \mathcal{V} (besides $\text{comp}(\bar{t})$) are recorded in this parameter, because aliased variables whose type is infinite (or which after having been expanded get bounded to a term containing variables whose type is infinite) allow us to detect useless cobasic sets, since it is always possible to find an instance of δ' which does not meet the equality constraints imposed by \bar{t} (case a)). Useless cobasic sets are then subsequently removed in steps 3 and 4, before $\text{empty2}(\Gamma', \delta)$ is called in step 5. The first pass over the cobasic sets ends in step 2 when condition $\mathcal{C}' = \emptyset$ holds. Note that when this condition holds, step 4 checks that a type expression denotes a finite set of terms, and there are

Algorithm 1 *empty1*

Input: a type-annotated term δ , a set of cobasic sets \mathcal{C} and a set Γ of triples of the form $(\delta_1, \mathcal{V}, \text{comp}(\bar{t}))$

Output: a boolean

```

1:  $\mathcal{C}' \leftarrow \{\text{comp}(\bar{t}) \in \mathcal{C} \mid \text{intersec}(\delta, \bar{t}) \not\subseteq \Lambda\}$ 
2: if  $\mathcal{C}' = \emptyset$  then
3:    $\Gamma' \leftarrow \{\xi \in \Gamma \mid \xi \equiv (\delta_1, \mathcal{V}, \text{comp}(\bar{t})), \text{intersec}(\delta, \bar{t}) \not\subseteq \Lambda\}$ 
4:    $\Gamma'' \leftarrow \{\xi \in \Gamma' \mid \xi \equiv (\delta_1, \mathcal{V}, \text{comp}(\bar{t})), \theta = \text{mgu}(\bar{t}_\delta, \bar{t}_{\delta_1}), \text{ and for all } x \in \mathcal{V},$ 
      $y \in \text{vars}(x\theta): \rho_\delta(y) \text{ is finite } \}$ 
5:   return  $\text{empty2}(\Gamma'', \delta)$ 
6: else if  $\text{included}(\delta, \bar{t})$  for some cobasic set  $\text{comp}(\bar{t})$  in  $\mathcal{C}'$  then
7:   return true
8: else
9:   select a cobasic set  $\text{comp}(\bar{t}) \in \mathcal{C}'$ 
10:   $\mathcal{C}'' \leftarrow \mathcal{C}' - \{\text{comp}(\bar{t})\}$ 
11:   $(\delta', \Delta) \leftarrow \text{expansion}(\delta, \text{comp}(\bar{t}))$ 
12:  if  $\text{included}(\delta', \bar{t})$  then
13:    return  $\bigwedge_{\delta'' \in \Delta} \text{empty1}(\mathcal{C}'', \delta'', \Gamma)$ 
14:  else
15:     $\mathcal{V} \leftarrow \text{aliased}(\delta', \bar{t})$ 
16:     $\theta' \leftarrow \text{mgu}(\bar{t}_{\delta'}, \bar{t})$ 
17:    if for some  $x \in \text{vars}(\delta')$  s.t.  $\rho_{\delta'}(x) = \mu: x \in \mathcal{V}$  or  $x\theta'$  is not a var. then
18:      return  $\text{empty1}(\mathcal{C}'', \delta, \Gamma)$ 
19:    else
20:       $\Gamma' \leftarrow \Gamma \cup \{(\delta', \mathcal{V}, \text{comp}(\bar{t}))\}$ 
21:      return  $\text{empty1}(\mathcal{C}'', \delta', \Gamma') \wedge \bigwedge_{\delta'' \in \Delta} \text{empty1}(\mathcal{C}'', \delta'', \Gamma)$ 
22:    end if
23:  end if
24: end if
```

Algorithm 2 *empty2*

Input: a type-annotated term δ and a set Γ of triples of the form $(\delta', \mathcal{V}, \text{comp}(\bar{t}))$

Output: a boolean

```
1: if  $\Gamma = \emptyset$  then
2:   return false
3: else
4:   select an item  $\xi \in \Gamma$ ; assume  $\xi \equiv (\delta', \mathcal{V}, \text{comp}(\bar{t}))$ 
5:    $\Gamma' \leftarrow \Gamma - \{\xi\}$ 
6:    $\sigma \leftarrow \text{mgu}(\bar{t}_{\delta'}, \bar{t}_{\delta})$ 
7:   if  $\text{included}(\delta, \bar{t})$  then
8:     return true
9:   else
10:    initialize a set  $\Delta$ 
11:    for all variables  $x \in \mathcal{V}$  do
12:      for all variables  $y$  such that  $y \in \text{vars}(x\sigma)$  do
13:         $\Delta \leftarrow \Delta \cup \{ \delta[y/t] \mid t \in \gamma(\rho_{\delta}(y)) \}$ 
14:      end for
15:    end for
16:     $\Delta' \leftarrow \{ \delta'' \in \Delta \mid \text{intersec}(\delta'', \bar{t}) \simeq A \}$ 
17:    if  $\Delta' = \emptyset$  then
18:      return true
19:    else
20:      return  $\bigwedge_{\delta'' \in \Delta'} \text{empty2}(\Gamma', \delta'')$ 
21:    end if
22:  end if
23: end if
```

straightforward algorithms to test this. The *empty2* function performs a second pass over the remaining cobasic sets, checking whether the constraints described previously in case a) hold.

Definition 18 (*empty2*(Γ, δ) **function**). *Given a type-annotated term δ , such that $\delta \not\sqsubseteq A$, and a set Γ of triples of the form $(\delta', \mathcal{V}, \text{comp}(\bar{t}))$ where:*

- δ' is a type-annotated term, such that $\delta' \not\sqsubseteq A$, and $\text{comp}(\bar{t})$ a cobasic set,
- $\text{vars}(\delta') \cap \text{vars}(\text{comp}(\bar{t})) = \emptyset$,
- for all $x \in \text{vars}(\delta')$, $x\theta$ is a variable, where $\theta = \text{mgu}(\bar{t}_{\delta'}, \bar{t})$ ($\rho_{\delta'}(x)$ can be any type, including μ),
- $v \in \mathcal{V}$ iff $v \in \text{vars}(\delta')$, $\rho_{\delta'}(v) \neq \mu$ and exists $v' \in \text{vars}(\delta')$, $v \neq v'$, such that $v\theta = v'\theta$ (i.e., \mathcal{V} is the set of variables in $\text{vars}(\delta')$ which are aliased with some other variable in $\text{vars}(\delta')$ by θ), and
- for all $x \in \mathcal{V}$, $\rho_{\delta'}(x)$ is finite (note that for all $v \in \text{vars}(\delta')$ such that $v \notin \mathcal{V}$, $\rho_{\delta'}(v)$ can be any type, including μ),

we define the function *empty2* in Algorithm 2, where $\delta[y/t]$ denotes an instance of type annotated term δ obtained by substituting variable y by term t .

The function $empty2(\Gamma, \delta)$ selects a cobasic set $comp(\bar{t})$ in Γ , and, if δ is not included in \bar{t} , then δ is expanded (in step 13) to a set of type-annotated terms Δ by substituting only “decision variables.” Such expansion ensures that every $\delta'' \in \Delta$ is either “included” in \bar{t} or “disjoint” with it. It also ensures that δ is not infinitely expanded: the type of such variables is finite. Note that, at step 13, necessarily $y \in vars(\delta)$, and $\rho_\delta(y)$ is finite. Note also that, at step 16, necessarily, for all $\delta'' \in \Delta$ and $\delta'' \notin \Delta'$, it holds that $\delta'' \sqsubseteq \bar{t}$. For this reason, $comp(\bar{t})$ is removed from the recursive call at step 20.

Soundness and Completeness Results

The function $empty(\delta, S)$ is sound and complete for *tuple-distributive regular types*. While sound, the function is not complete for regular types in general. However, our experience (as we will see in Section 5) is that it is fairly accurate in practice. Note that our applications do not require analysis algorithms to be complete (impossible in general) but rather always safe and as accurate as possible [14].

We now give some instrumental lemmas for proving the termination and correctness of the presented algorithm.

Lemma 1. *Let δ be a type-annotated term, C a set of cobasic sets, and $comp(\bar{t}) \in C$ an useless cobasic set for determining whether $\delta \otimes C \simeq A$. $\delta \otimes C \simeq A$ if and only if $\delta \otimes (C - \{comp(\bar{t})\}) \simeq A$.*

Proof. By definition of useless cobasic set we have that if $\delta \otimes C \simeq A$, then $\delta \otimes (C - \{comp(\bar{t})\}) \simeq A$. Also, if $\delta \otimes (C - \{comp(\bar{t})\}) \simeq A$, then obviously $\delta \otimes C \simeq A$ (note that $(\delta \otimes C) \sqsubseteq (\delta \otimes (C - \{comp(\bar{t})\}))$). ■

Lemma 2. *Let δ be a type-annotated term, C a set of cobasic sets, and $comp(\bar{t}) \in C$ a cobasic set. If $intersec(\delta, \bar{t}) = A$, then $comp(\bar{t})$ is useless for determining whether $\delta \otimes C \simeq A$.*

Note that the opposite is not true in general: there can be useless cobasic sets in C whose tuples of terms are not disjoint with δ .

Proof. If $intersec(\delta, \bar{t}) = A$, then $\delta \otimes comp(\bar{t}) \simeq \delta$ (since $Den(\delta) \cap Den(comp(\bar{t})) = Den(\delta)$), and hence $\delta \otimes C \simeq \delta \otimes (C - \{comp(\bar{t})\})$. ■

Lemma 3. *Let δ and C be a type-annotated term and a set of cobasic sets respectively. $\delta \otimes C \not\simeq A$ iff there is a type-annotated term instance δ' of δ such that $\delta' \otimes \bar{t} \simeq A$ for all cobasic sets $comp(\bar{t}) \in C$.*

Proof. Trivial. ■

Theorem 4. *Let δ be a type-annotated term, C a set of cobasic sets, and $comp(\bar{t}) \in C$ a cobasic set. Let $(\delta', \Delta) = expansion(\delta, comp(\bar{t}))$ and $\mathcal{V} = aliased(\delta', \bar{t})$. Assume that $\delta' \not\sqsubseteq \bar{t}$ and for all $comp(\bar{t}_1) \in C$ it holds that $\delta \not\sqsubseteq \bar{t}_1$ and $\delta \otimes \bar{t}_1 \not\simeq A$. Then, if for some $x \in vars(\delta')$, it holds that:*

- $\rho_{\delta'}(x)$ is an infinite function symbol type, and,

– $x \in \mathcal{V}$ or $x\theta$ is not a variable, where $\theta = mgu(\bar{t}_{\delta'}, \bar{t})$,

then $comp(\bar{t})$ is useless for determining whether $\delta \otimes \mathcal{C} \simeq \Lambda$.

Proof. We are going to prove that: if $\delta \otimes (\mathcal{C} - \{comp(\bar{t})\}) \not\simeq \Lambda$, then $\delta \otimes \mathcal{C} \not\simeq \Lambda$. If $\delta \otimes (\mathcal{C} - \{comp(\bar{t})\}) \not\simeq \Lambda$, then according to Lemma 3, there is a type-annotated term instance δ_2 of δ such that $\delta_2 \otimes \bar{t}_2 \simeq \Lambda$ for all cobasic sets $comp(\bar{t}_2) \in (\mathcal{C} - \{comp(\bar{t})\})$. We are going to show how to use δ_2 to construct an instance δ_3 of δ such that $\delta_3 \otimes \bar{t}_3 \simeq \Lambda$ for all cobasic sets $comp(\bar{t}_3) \in \mathcal{C}$, and thus (by Lemma 3) $\delta \otimes \mathcal{C} \not\simeq \Lambda$.

By definition of the function *expansion* we have that $\delta \simeq (\bigoplus_{\delta'' \in \Delta} \delta'') \oplus \delta'$. Then, we have two cases:

1. δ_2 is a type-annotated term instance of some $\delta'' \in \Delta$, in which case we take $\delta_3 = \delta_2$. Clearly, since $\delta'' \otimes \bar{t} \simeq \Lambda$ (by definition of the function *expansion*), we have that $\delta_2 \otimes \bar{t} \simeq \Lambda$. We also have (by hypothesis and because δ_2 is a type-annotated term instance of δ) that $\delta_2 \otimes \bar{t}_2 \simeq \Lambda$ for all cobasic sets $comp(\bar{t}_2) \in (\mathcal{C} - \{comp(\bar{t})\})$. Thus $\delta_3 \otimes \bar{t}_3 \simeq \Lambda$ for all cobasic sets $comp(\bar{t}_3) \in \mathcal{C}$.
2. δ_2 is a type-annotated term instance of δ' .

Note that the condition “ $x \in \mathcal{V}$ or $x\theta$ is not a variable” (recall that $\theta = mgu(\bar{t}_{\delta'}, \bar{t})$), represents equality constraints which any instance of both, δ' and \bar{t} must meet. More concretely, “ $x \in \mathcal{V}$ ” means that there is at least one equality constraint between x and some other variable in \mathcal{V} ; and “ $x\theta$ is not a variable,” means that the subterm to which x is bound in any instance of both, δ' and \bar{t} , must unify with $x\theta$ (we mean “type unification,” which takes into account the type of the variables in such subterm, if any). Since $\rho_{\delta'}(x)$ is an infinite function symbol type, it is always possible to construct an instance δ_3 of δ' by binding x to a term s which does not meet the former constraints, and thus, $\delta_3 \otimes \bar{t} \simeq \Lambda$ (and also $\delta_3 \otimes \bar{t}_3 \simeq \Lambda$ for all cobasic sets $comp(\bar{t}_3) \in \mathcal{C}$).

Let us see in detail a possible way to construct δ_3 :

- Let s be a ground term whose main function symbol is new,⁶ i.e., it does not appear in δ_2 nor in \mathcal{C} (this is always possible since $\rho_{\delta'}(x)$ is an infinite function symbol type);
- Since δ_2 is an instance of δ' , we have that $\bar{t}_{\delta_2} = \bar{t}_{\delta'}\theta_2$ for some substitution θ_2 ,
- Let $\theta_3 = (\theta_2 - \{x \leftarrow x\theta_2\}) \cup \{x \leftarrow s\}$ (i.e. we obtain θ_3 by replacing the binding for x in θ_2 by another one which binds x to s);
- Let $\bar{t}_{\delta_3} = \bar{t}_{\delta'}\theta_3$.
- Let ρ_{δ_3} be the type assignment that assigns to each variable in \bar{t}_{δ_3} the type that such variable has in ρ_{δ_2} (i.e., $\rho_{\delta_3}(v) = \rho_{\delta_2}(v)$ for any $v \in vars(\bar{t}_{\delta_3})$). Note that since $\bar{t}_{\delta_2} = \bar{t}_{\delta'}\theta_2$, $\bar{t}_{\delta_3} = \bar{t}_{\delta'}\theta_3$ and $vars(v\theta_3) \subseteq vars(v\theta_2)$ for any variable in the domain of θ_2 and θ_3 (both substitutions have the same domain), we have that $vars(\bar{t}_{\delta_3}) \subseteq vars(\bar{t}_{\delta_2})$.

⁶ Constant symbols are considered to be function symbols of arity zero.

Since the main function symbol of s does not appear in δ_2 nor in \mathcal{C} , the equality constraints which are not met by δ_2 and that imply that $\delta_2 \otimes \bar{t}_2 \simeq A$ for all cobasic sets $\text{comp}(\bar{t}_2) \in (\mathcal{C} - \{\text{comp}(\bar{t})\})$, are not met by δ_3 neither. Thus, we also have that $\delta_3 \otimes \bar{t}_3 \simeq A$ for all cobasic sets $\text{comp}(\bar{t}_3) \in (\mathcal{C} - \{\text{comp}(\bar{t})\})$. Since $\delta_3 \otimes \bar{t} \simeq A$, we conclude that $\delta_3 \otimes \bar{t}_3 \simeq A$ for all cobasic sets $\text{comp}(\bar{t}_3) \in \mathcal{C}$. ■

Lemma 4. *Let δ and \mathcal{C} be a type-annotated term and a set of cobasic sets respectively. If there is a cobasic set $\text{comp}(\bar{t}) \in \mathcal{C}$ such that $\delta \sqsubseteq \bar{t}$, then $\delta \otimes \mathcal{C} \simeq A$.*

Proof. Trivial. ■

Lemma 5. *In any call of the form $\text{empty2}(\Gamma, \delta)$ and for any triple $(\delta_i, \mathcal{V}_i, \text{comp}(\bar{t}_i)) \in \Gamma$, where $1 \leq i \leq n$, it holds that δ is a type-annotated term instance of δ_i , i.e., $\delta \sqsubseteq \delta_i$ and there is a substitution θ_i such that $\bar{t}_\delta = \bar{t}_{\delta_i} \theta_i$ (note that $\theta_i = \text{mgu}(\bar{t}_\delta, \bar{t}_{\delta_i})$).*

Proof. Trivial. By observing the way in which the items $(\delta_i, \mathcal{V}_i, \text{comp}(\bar{t}_i)) \in \Gamma$, for $1 \leq i \leq n$, are created in function empty1 , we have that: $(\delta_1, \Delta_1) = \text{expansion}(\delta', \bar{t})$, for some δ' and \bar{t} , $(\delta_2, \Delta_2) = \text{expansion}(\delta_1, \bar{t}_1)$, ..., $(\delta_n, \Delta_n) = \text{expansion}(\delta_{n-1}, \bar{t}_{n-1})$. ■

Lemma 6. *Let δ and \mathcal{C} be a type-annotated term and a set of cobasic sets respectively. Let $\delta_1, \dots, \delta_n$ be a set of type-annotated terms which constitute a partition of δ (to which δ has been expanded by using the function expansion), i.e., $\delta \simeq \delta_1 \oplus \dots \oplus \delta_n$. Then, $\delta \otimes \mathcal{C} \simeq A$ if and only if for all i , $1 \leq i \leq n$, $\delta_i \otimes \mathcal{C} \simeq A$.*

Proof. It can be easily proved by using the $\text{Den}(S)$ function over elementary sets (which gives sets of tuples of Herbrand terms) and some well known set theory results, or based on the fact that \oplus , \otimes , and comp constitute a Boolean algebra. ■

Lemma 7. *$\text{empty2}(\Gamma, \delta)$ terminates.*

Proof. The number of type-annotated terms in which δ is expanded (in step 13 of Algorithm 2) is finite, since they are created by expanding a finite number of variables whose type is finite, thus, the number of recursive calls $\text{empty2}(\Gamma', \delta'')$ (in step 20 of Algorithm 2) is finite (i.e. Δ' is a finite set), and, the number of items in Γ' in each of them decreases. ■

Lemma 8. *If $\text{empty2}(\Gamma, \delta)$ return **true**, then $\delta \otimes \mathcal{C} \simeq A$, where $\mathcal{C} = \{\text{comp}(\bar{t}) \mid (\delta', \mathcal{V}, \text{comp}(\bar{t})) \in \Gamma \text{ for some } \delta' \text{ and } \mathcal{V}\}$ (i.e., \mathcal{C} is the set of cobasic sets in Γ).*

Proof. It is easy to prove by induction on the depth of recursion of empty2 upon termination that δ can be expanded to a set of type-annotated terms $\delta_1, \dots, \delta_n$, which constitute a partition of it (i.e., $\delta \simeq \delta_1 \oplus \dots \oplus \delta_n$), and for all i , $1 \leq i \leq n$, exists a cobasic set $\text{comp}(\bar{t}_i)$ in \mathcal{C} , such that $\delta_i \sqsubseteq \bar{t}_i$. Thus, using Lemmas 4 and 6 we conclude that $\delta \otimes \mathcal{C} \simeq A$. ■

Lemma 9. *If $\text{empty2}(\Gamma, \delta)$ returns **false**, then $\delta \otimes \mathcal{C} \not\simeq \Lambda$, where $\mathcal{C} = \{\text{comp}(\bar{t}) \mid (\neg, \neg, \text{comp}(\bar{t})) \in \Gamma\}$.*

Proof. It can be proved by induction on the *depth* of recursion of empty2 upon termination that there is a type-annotated term instance of δ , δ_1 such that:

1. for all $x \in \text{vars}(\bar{t}_\delta)$, if $\rho_\delta(x)$ is infinite, then $x\theta = x$, where $\bar{t}_{\delta_1} = \bar{t}_\delta\theta$ for some substitution θ (i.e., δ_1 is the result of expanding only variables of δ whose type is finite), and
2. $\delta_1 \otimes \bar{t} \simeq \Lambda$ for all $\text{comp}(\bar{t}) \in \mathcal{C}$, and thus, by Lemma 3, $\delta \otimes \mathcal{C} \not\simeq \Lambda$.

Let us see it in more detail. In the base case (*depth* = 0), we have that $\Gamma = \emptyset$, and the lemma holds trivially for $\delta_1 = \delta$. In the recursive case, assume that *depth* = K , $K > 0$, and the lemma holds for all recursive calls of depth less than K . Then, by induction hypothesis (and the meaning of the conjunction), in step 20 of Algorithm 2, exists an instance δ_2 of some type-annotated term δ'' , where $\delta'' \in \Delta'$, such that $\delta_2 \otimes \bar{t}_2 \simeq \Lambda$ for all $\text{comp}(\bar{t}_2)$ such that $(\neg, \neg, \text{comp}(\bar{t}_2)) \in \Gamma'$, where $\Gamma' = \Gamma - \{(\delta', \mathcal{V}, \text{comp}(\bar{t}))\}$. Since $\delta'' \in \Delta'$, we have that $\delta'' \otimes \bar{t} \simeq \Lambda$ (see step 16 in Algorithm 2), and thus $\delta_2 \otimes \bar{t} \simeq \Lambda$ (because δ_2 is an instance of δ''). It is clear that condition 1 holds, since only variables of δ whose type is finite are expanded (see step 13 of Algorithm 2). Thus, (and since δ_2 is an instance of δ'' , and δ'' an instance of δ) we take $\delta_1 = \delta_2$. ■

Theorem 5. *$\text{empty1}(\mathcal{C}, \delta, \Gamma)$ terminates and, if all types in δ and Γ are tuple-distributive regular types, then returns **true** iff $\delta \otimes \mathcal{C}_1 \simeq \Lambda$, where $\mathcal{C}_1 = \mathcal{C} \cup \{\text{comp}(\bar{t}) \mid (\delta_1, \mathcal{V}, \text{comp}(\bar{t})) \in \Gamma, \text{ for some } \delta_1 \text{ and } \mathcal{V}\}$.*

Proof. Termination can be proved based on:

- The initial problem is reduced to a finite number of subproblems. The number of subproblems is bound by the number of type-annotated terms to which δ is expanded using the function *expansion*,
- the number of cobasic sets in \mathcal{C} is finite,
- the number of cobasic sets in \mathcal{C}'' decreases in each recursive call of the form $\text{empty1}(\mathcal{C}'', \neg, \neg)$, and
- $\text{empty2}(\Gamma', \delta)$ terminates (Lemma 7).

Correctness and completion can be proved by induction on the depth of recursion of empty1 upon termination, based on:

- the correctness and completion of the function $\text{empty2}(\Gamma', \delta)$ (Lemmas 8 and 9).
- The results returned by the function empty1 in the base cases are correct. Namely, in step 1 of function empty1 , useless cobasic sets are removed (by Lemma 2), thus, according to Lemma 1 the initial problem is correctly reduced to an equivalent problem. In step 6, the returned value is correct according to Lemma 4. Finally, in step 2 of Algorithm 1 (before calling function empty2) useless cobasic sets are removed. Let us see in detail why these cobasic sets can be correctly removed:

- If $\text{empty2}(\Gamma', \delta)$ returns **false**, it follows from Lemmas 9 and 3 that exists a type-annotated term instance of δ , δ_2 , such that $\delta_2 \otimes \bar{t} \simeq A$ for all $(-, -, \text{comp}(\bar{t})) \in \Gamma'$. Also, for all $v \in \text{vars}(\delta)$, if $\rho_\delta(v)$ is an infinite type, then $v\theta = v$, where $\bar{t}_{\delta_2} = \bar{t}_\delta\theta$ (i.e., δ_2 has been created by expanding only variables of δ whose type is finite, and thus $\rho_\delta(v) = \rho_{\delta_2}(v)$ and $\rho_{\delta_2}(v)$ is an infinite type). Let $\Gamma_1 = \Gamma - \Gamma'$ (i.e. Γ_1 is the set of triples removed in step 2 of Algorithm 1). It is clear that any cobasic set $\text{comp}(\bar{t})$ such that $(\delta_1, \mathcal{V}, \text{comp}(\bar{t})) \in \Gamma_1$ and $\text{intersec}(\delta, \bar{t}) \simeq A$, is useless (Lemma 2). Let $\Gamma_2 = \{(\delta_1, \mathcal{V}, \text{comp}(\bar{t})) \in \Gamma_1 \mid \text{intersec}(\delta, \bar{t}) \not\simeq A\}$. We can create a type-annotated term δ_3 which is an instance of δ_2 such that for all $(-, -, \text{comp}(\bar{t}_3)) \in \Gamma$, $\delta_3 \otimes \bar{t}_3 \simeq A$, as follows:
 - * We have that for all $\xi_i \in \Gamma_2$, where $\xi_i = (\delta'_i, \mathcal{V}_i, \text{comp}(\bar{t}_i))$, there is a variable x_i , $x_i \in \mathcal{V}_i$ and $x_i \in \text{vars}(\delta'_i)$, and there is another variable y_i , $y_i \in \text{vars}(\delta)$, $y_i \in \text{vars}(\delta_2)$ and $y_i \in \text{vars}(x_i\sigma_i)$, where $\sigma_i = \text{mgu}(\bar{t}_{\delta'_i}, \bar{t}_\delta)$ and $\bar{t}_\delta = \bar{t}_{\delta'_i}\sigma_i$ (note that δ is a type-annotated term instance of δ'_i , according to Lemma 5), and $\rho_\delta(y_i)$ is an infinite type. Thus, the variable y_i has not been expanded by $\text{empty2}(\Gamma', \delta)$ and it appears in δ_2 (i.e., $y_i\theta = y_i$, where $\theta = \text{mgu}(\bar{t}_\delta, \bar{t}_{\delta_2})$, and $\rho_{\delta_2}(y_i)$ is an infinite type).
 - * Now, take δ_2 and bind all the formerly mentioned variables $y_i \in \text{vars}(\delta_2)$ such that $\xi_i \in \Gamma_2$, to ground Herbrand terms s_i according with their types (i.e. $s_i \in \gamma(\rho_{\delta_2}(y_i))$), obtaining the instance δ_3 so that the following condition is met (this is possible because the type of y_i , $\rho_{\delta_2}(y_i)$, is infinite): for all ξ_1, ξ_2, v such that $\xi_1, \xi_2 \in \Gamma_2$, $\xi_1 = (\delta'_1, \mathcal{V}_1, -)$, $\xi_2 = (\delta'_2, \mathcal{V}_2, -)$, $v \in \mathcal{V}_1$, and $y_1 = y_2$, then $v\theta_1 \neq x_1\theta_1$, where $\theta_1 = \text{mgu}(\bar{t}_{\delta'_1}, \bar{t}_{\delta_3})$ (i.e., $t_{\delta_3} = \bar{t}_{\delta'_1}\theta_1$).
- The decomposition (or reduction) of the initial problem into one or more subproblems and the combination of the results of those subproblems in order to obtain the result of the original problems is correct and complete. In step 12 of function empty1 , the decomposition in subproblems is correct and complete based on Lemmas 4 (because $\text{included}(\delta', \bar{t})$), and 6 (note that function $\text{expansion}(\delta, \text{comp}(\bar{t}))$ returns a complete partition of δ). In step 17 of Algorithm 1 the cobasic set $\text{comp}(\bar{t})$ is useless (according to Theorem 4) and thus removed. Finally, in step 21 of Algorithm 1, the decomposition in subproblems is correct and complete based on Lemma 6. \blacksquare

The mutual exclusion algorithm we present is complete for *tuple-distributive regular types*:

Theorem 6. *Let δ be a type-annotated term in which all types are tuple-distributive regular types, and β a minset, $\beta \not\simeq A$. Then $\text{empty}(\delta, \beta)$ terminates, and returns **true** if and only if $\delta \otimes \beta \simeq A$.*

Proof. Assume that $\beta = \bar{t}_0 \otimes C$ (where \bar{t}_0 is a tuple of terms, and C a set of cobasic sets). The result follows from Theorem 5 and the following observation: if $\text{included}(\bar{t}_0, \delta') = \mathbf{true}$, then $\bar{t}_0 \sqsubseteq \delta'$. Since $\bar{t}_0 \sqsubseteq \delta'$ iff $\bar{t}_0 \sqsubseteq \delta \otimes \bar{t}_0$ iff $\bar{t}_0 \simeq \delta \otimes \bar{t}_0$, we have that $(\delta \otimes \beta) \simeq (\delta \otimes \bar{t}_0 \otimes C) \simeq (\bar{t}_0 \otimes C) \simeq \beta \not\simeq A$. \blacksquare

While sound, the algorithm is not complete for regular types in general (though we believe it is fairly accurate in practice):

Theorem 7. *Let δ be a type-annotated term where all types are regular types, and S a minset. Then $\text{empty}(\delta, S)$ terminates, and if it returns **true** then $\delta \otimes S \simeq A$.*

One reason for imprecision in the case of non tuple-distributive regular types is that the function $\text{intersec}(\delta, A)$, computes a superset of the exact intersection when we deal with general regular types (this result can be derived from the work of [4]). Another reason comes from the use of the function $\text{expansion}(\delta, \text{comp}(t))$ to partition the type-annotated term δ in the boolean function $\text{empty1}(\mathcal{C}, \delta, \emptyset)$. Given a pair (δ', Δ) where δ' is a type-annotated term, and Δ is a set of type-annotated terms, we assume that all type-annotated terms in Δ are disjoint with the tuple of terms of the cobasic set $\text{comp}(t)$, but this is not true for general regular types, and, consequently, precision may be lost. A possible solution in order to obtain a complete algorithm for general regular types would be to rewrite the type annotated term which represents the input type of a predicate as a union of type annotated terms containing only tuple-distributive types, and then apply the above described mutual exclusion algorithm for each of the elements of the union.

4.2 Checking Mutual Exclusion in Linear Arithmetic

In this section, we give an algorithm for checking whether two linear arithmetic tests $\tau_i(\bar{x})$ and $\tau_j(\bar{x})$ are exclusive w.r.t. the type assignment of **int** to each variable in \bar{x} . This amounts to determining whether $(\exists \bar{x})(\tau_i(\bar{x}) \wedge \tau_j(\bar{x}))$ is unsatisfiable. The system $\tau_i(\bar{x}) \wedge \tau_j(\bar{x})$ can be transformed into disjunctive normal form as in equation (1) below, where each of the tests $\phi_{kl}(\bar{x})$ is of the form $\phi_{kl}(\bar{x}) \equiv a_0 + a_1x_1 + \dots + a_px_p \text{ ? } 0$, with $\text{?} \in \{=, <, \leq, >, \geq\}$. For this transformation, note that a test $a_0 + a_1x_1 + \dots + a_px_p \neq 0$ can be written in terms of two tests involving only ' $>$ ' and ' $<$ ', as in equation (2).

$$\begin{aligned} (\tau_i(\bar{x}) \wedge \tau_j(\bar{x})) &= \bigvee_{k=1}^n \bigwedge_{l=1}^m \phi_{kl}(\bar{x}) & (\sum_{i=0}^p a_i x_i > 0) \vee (\sum_{i=0}^p a_i x_i < 0) \\ (1) \text{ Disjunctive normal form} & & (2) \text{ Rewriting of disequalities} \end{aligned}$$

The resulting system, transformed to disjunctive normal form, defines a set of integer programming problems: the answer to the original mutual exclusion problem is “yes” if and only if none of these integer programming problems has a solution. Since a test can give rise to at most finitely many integer programming problems in this way, it follows that the mutual exclusion problem for linear integer tests is decidable. Since determining whether an integer programming problem is solvable is NP-complete [9], the following complexity result is immediate:

Theorem 8. *The mutual exclusion problem for linear arithmetic tests over the integers is co-NP-hard.*

It should be noted, however, that the vast majority of arithmetic tests encountered in practice tend to be fairly simple: our experience has been that tests involving more than two variables are rare. The solvability of integer programs in the case where each inequality involves at most two variables, i.e., is of the form $ax + by \leq c$, can be decided efficiently in polynomial time by examining the loops in a graph constructed from the inequalities [1]. The integer programming problems that arise in practice, in the context of mutual exclusion analysis, are therefore efficiently decidable.

The ideas explained in this section for linear arithmetic over integers extend directly to linear tests over the reals, which turn out to be computationally somewhat simpler.

4.3 Checking Mutual Exclusion: Putting it All Together

Consider a predicate p defined by n clauses C_1, \dots, C_n , with input tests $\tau_1(\bar{x}), \dots, \tau_n(\bar{x})$ respectively. Assume, without loss of generality, that each $\tau_k(\bar{x})$, $1 \leq k \leq n$ is a conjunction of primitive tests (note that it is always possible to obtain an equivalent sequence of clauses where disjunctions have been removed). Assume also that each $\tau_k(\bar{x})$, $1 \leq k \leq n$, is written as $\tau_k^H \wedge \tau_k^A$, where τ_k^H and τ_k^A are a conjunction of primitive unification and arithmetic tests respectively (i.e., we write arithmetic tests after unification tests). Consider also each τ_k^H written as a minset β_k (the function *test2minset*, given in Definition 10, returns the minset representation of a test).

Assume that predicate p has type `type[p]`. In order to check whether p is mutually exclusive (i.e., its clauses are mutually exclusive w.r.t. the type assignment $\bar{x} : \text{type}[p]$) we need to solve the problem of determining whether any pair of tests $\tau_i(\bar{x})$ and $\tau_j(\bar{x})$, $1 \leq i, j \leq n$, $i \neq j$, is exclusive w.r.t. $\bar{x} : \text{type}[p]$.

Before describing a sufficient condition for ensuring that these tests are exclusive, we define some instrumental elements. Let β_{ij} be the minset intersection of β_i and β_j . Let θ_i (resp. θ_j), be the most general unifier of the tuple of terms of β_{ij} and β_i (resp. β_j). That is, if $\beta_i \equiv \bar{t}_i \otimes C_i$, $\beta_j \equiv \bar{t}_j \otimes C_j$, and $\beta_{ij} \equiv \bar{t}_{ij} \otimes C_{ij}$, then $\theta_i = mgu(\bar{t}_i, \bar{t}_{ij})$, $\bar{t}_{ij} \equiv \bar{t}_i \theta_i$, $\theta_j = mgu(\bar{t}_j, \bar{t}_{ij})$, $\bar{t}_{ij} \equiv \bar{t}_j \theta_j$ (note that there exists a substitution μ_{ij} , such that $\mu_{ij} = mgu(\bar{t}_i, \bar{t}_j)$). Let ρ be the type assignment $\bar{x} : \text{type}[p]$ but written as a type-annotated term δ . We have that the tests $\tau_i(\bar{x})$ and $\tau_j(\bar{x})$, are exclusive w.r.t. ρ if:

1. $\delta \otimes \beta_i \otimes \beta_j \simeq \perp$ (which can be checked as explained in Section 4.1), or
2. $\delta \otimes \beta_i \otimes \beta_j \not\simeq \perp$ and $\tau_i^A \theta_i \wedge \tau_j^A \theta_j$ is unsatisfiable (which can be checked as explained in Section 4.2).

Example 10. Reconsider Example 5 with predicate `part/4` from the quicksort program of Figure 1. We had reduced the mutual exclusion problem to two sub-problems: a) checking that the tests $\mathbf{L} = []$ and $\mathbf{L} = [\mathbf{E}|\mathbf{R}]$ are exclusive w.r.t. type assignment ρ , and b) checking that the tests $\mathbf{E} < \mathbf{C}$ and $\mathbf{E} \geq \mathbf{C}$ are exclusive w.r.t. ρ . In this case, we have that δ is $((\mathbf{L}, \mathbf{C}), (\mathbf{L} : \text{intlist}, \mathbf{C} : \text{int}))$. Also, $\beta_1 \equiv ([], \mathbf{C})$, $\beta_2 \equiv ([\mathbf{E}|\mathbf{R}], \mathbf{C})$, and $\beta_3 \equiv ([\mathbf{E}|\mathbf{R}], \mathbf{C})$. We now have that `part/4` is

mutually exclusive because: $\delta \otimes \beta_i \otimes \beta_j \simeq A$, for $i = 1$ and $j \in \{2, 3\}$, and (although $\delta \otimes \beta_2 \otimes \beta_3 \not\simeq A$) also $\mathbf{E} < \mathbf{C} \wedge \mathbf{E} \geq \mathbf{C}$ is unsatisfiable (note that $\beta_{2,3} \equiv ([\mathbf{E}|\mathbf{R}], \mathbf{C})$, and θ_2 and θ_3 are the identity).

4.4 Checking Mutual Exclusion: Dealing with the Cut

The presence of a pruning operator (cut) in program clauses can help the detection of mutual exclusion. In order to take the cut into account, we simply redefine the concept of mutually exclusive clauses in Definition 4 as:

Definition 19 (mutual exclusion in the presence of cut). *Let C_1, \dots, C_n , $n > 0$, be a sequence of clauses, with input tests τ_1, \dots, τ_n respectively. Let ρ be a type assignment. We say that C_1, \dots, C_n is mutually exclusive w.r.t. ρ if either, $n = 1$, or, for every pair of clauses C_i and C_j , $1 \leq i, j \leq n$, $i \neq j$: C_i has a cut and $i < j$, or C_j has a cut and $j < i$, or $\tau_i(\bar{x})$ and $\tau_j(\bar{x})$ are exclusive w.r.t. ρ .*

We also have to take into account that the pruning operator introduces implicit tests. Consider a predicate p defined by a sequence of n clauses C_1, \dots, C_n , with input tests $\tau_1(\bar{x}), \dots, \tau_n(\bar{x})$ respectively. Let I be the set of indexes k of clauses C_k which have a cut and are before the clause C_i (i.e., $k < i$). Let τ_k^b be the test (conjunction of tests) that is before the cut in clause C_k (i.e., $\tau_k \equiv \tau_k^b \wedge \tau_k^a$, where τ_k^a is the test that is after the cut in clause C_k). Now, instead of considering the test τ_i , for $1 \leq i \leq n$, in Definition 19, we take the test τ_i^c defined as follows:

$$\tau_i^c = \begin{cases} \tau_i & \text{if } I = \emptyset \\ (\bigwedge_{k \in I} \neg \tau_k^b) \wedge \tau_i & \text{otherwise.} \end{cases}$$

Example 11. Consider predicate **abs**/2 mentioned in page 7. Usually, this predicate is defined with a cut in the first clause and no check in the second. In this case, the test for the second clause will be $\neg \mathbf{X} \geq 0$.

Note that the introduction of negation in the tests τ_i^c is not a problem, since it is always possible to reduce the problem of determining whether a pair of tests τ_i^c and τ_j^c are exclusive w.r.t. a given type assignment to one or more exclusion subproblems where the pair of tests involved in each subproblem are conjunctions of primitive tests (transforming tests to disjunctive normal form).

5 A Prototype Implementation

In order to evaluate the effectiveness and efficiency of our approach to determinacy analysis we have constructed a prototype which performs such analysis in an automatic way. The system takes Prolog programs as input,⁷ which include a module definition in the standard way. In addition, the types and modes

⁷ In fact, the input language currently supported includes also a number of extensions—such as functions or feature terms—which are translated by the first (expansion) passes of the Ciao compiler to clauses, possibly with cut.

Table 1. Accuracy and efficiency of the determinacy analysis (times in mS).

Program	N	D (%)	M (%)	C	T_D	T_M	T_T
<i>Hanoi</i>	2	2 (100)	2 (100)	N/A	48	55	103
<i>Fib</i>	1	1 (100)	1 (100)	N/A	16	21	37
<i>Mmatrix</i>	3	3 (100)	3 (100)	N/A	24	39	63
<i>Tak</i>	1	1 (100)	1 (100)	N/A	24	23	47
<i>Subs</i>	1	1 (100)	1 (100)	N/A	12	16	28
<i>Reverse</i>	2	2 (100)	2 (100)	N/A	21	20	41
<i>Qsort</i>	3	3 (100)	3 (100)	3 (100)	40	34	74
<i>Qsort2</i>	5	5 (100)	5 (100)	5 (100)	64	43	107
<i>Queens</i>	6	3 (50)	5 (83)	2 (33)	65	36	101
<i>Gabriel</i>	20	6 (30)	11 (55)	4 (20)	308	241	549

<i>Plan</i>	16	8 (50)	12 (75)	3 (19)	402	811	1213
<i>Credit</i>	25	18 (72)	21 (84)	16 (64)	1032	321	1353
<i>Pg</i>	10	6 (60)	9 (90)	6 (60)	372	177	549
Mean	—	71%	85%	61%	24 (/p)	31 (/p)	55 (/p)

of the arguments of exported predicates are either given or obtained from other modules during modular type and mode analysis (including the intervening type definitions). The system uses the CiaoPP PLAI analyzer to derive mode information, using, for the reported experiments, the Sharing+Freeness domain [26], and the *eterns* domain to derive the types of predicates [33]. The resulting type- and mode-annotated programs are then analyzed using the algorithms presented for Herbrand and linear arithmetic tests.

Herbrand mutual exclusion is checked by a naive direct implementation of the analyses presented. Testing of mutual exclusion for linear arithmetic tests is implemented directly using the Omega test [28]. This test determines whether there is an integer solution to an arbitrary set of linear equalities and inequalities, referred to as a problem.

We have tested the prototype first on a number of simple standard benchmarks, and then on more complex ones. The latter are taken from those used in the cardinality analysis of Braem *et al.* [2], which, as mentioned in Section 1, is the closest related previous work that we are aware of. In the case of *Kalah*, we have inserted the missing cuts as is also done in [2], to make the comparison meaningful. Some relevant results of these tests are presented in Table 1. **Program** lists the program names, **N** the number of predicates in the program, **D** the number of them detected by the analysis as deterministic, **M** the number of predicates whose tests are mutually exclusive, **C** the number of deterministic predicates detected in [2], **T_D** the time required by the determinacy analysis (Ciao/CiaoPP version 1.13, rev 10683, on an Intel Pentium M 1.86GHz, 1Gb of RAM memory, running Ubuntu Linux 8.04, and averaging several runs, eliminating the best and worst values), **T_M** the time required to derive the modes and types, and **T_T** the total analysis time (all times are in milliseconds). Averages

(per predicate in the case of analysis time) are also provided in the last row of the table.

The results are quite encouraging, showing that the developed analysis is fairly accurate. The analysis is more powerful in some cases than the cardinality analysis [2], and at least as accurate in the others. It is pointed out in [2] that determinacy information can be improved by using a more sophisticated type domain. This is also applicable to our analysis, and the types inferred by our system are similar to those used in [2]. The determinacy analysis times are also encouraging, despite the currently relatively naive implementation of the system (for example, the call to the omega test is done by calling an external process). The overall analysis times are also reasonable, even when including the type and mode analysis times, which are in any case very useful in other parts of the compilation process.

6 Conclusion

We have proposed an analysis for detecting procedures and goals that are deterministic (i.e., that produce at most one solution at most once), or predicates whose clause tests are mutually exclusive, even if they are not deterministic (because they call other predicates which are nondeterministic). Our approach has advantages w.r.t. previous approaches in that it provides an algorithm for detecting mutual exclusion and it handles disunification tests on the Herbrand domain and arithmetic tests.

We have implemented the proposed analysis and integrated it into the CiaoPP system, which also infers automatically the mode and type information that the proposed analysis takes as input. The results of the experiments performed on this implementation show that the analysis is fairly accurate and efficient, providing more accurate or similar results, regarding accuracy, than previous proposals, while offering substantially higher automation, since typically no information is needed from the user.
